

# ON STOCHASTIC AND DETERMINISTIC QUASI-NEWTON METHODS FOR NONSTRONGLY CONVEX OPTIMIZATION: ASYMPTOTIC CONVERGENCE AND RATE ANALYSIS\*

FARZAD YOUSEFIAN<sup>†</sup>, ANGELIA NEDIĆ<sup>‡</sup>, AND UDAY V. SHANBHAG<sup>§</sup>

**Abstract.** Motivated by applications arising from large-scale optimization and machine learning, we consider stochastic quasi-Newton (SQN) methods for solving unconstrained convex optimization problems. Much of the convergence analysis of SQN methods, in both full and limited-memory regimes, requires the objective function to be strongly convex. However, this assumption is fairly restrictive and does not hold in many applications. To the best of our knowledge, no rate statements currently exist for SQN methods in the absence of such an assumption. Furthermore, among the existing first-order methods for addressing stochastic optimization problems with merely convex objectives, techniques equipped with provable convergence rates employ averaging. However, this averaging technique has a detrimental impact on inducing sparsity. Motivated by these gaps, we consider optimization problems with non-strongly convex objectives with Lipschitz but possibly unbounded gradients. The main contributions of the paper are as follows: (i) To address large-scale stochastic optimization problems, we develop an iteratively regularized stochastic limited-memory BFGS (IRS-LBFGS) algorithm, where the step size, regularization parameter, and the Hessian inverse approximation are updated iteratively. We establish convergence of the iterates (with no averaging) to an optimal solution of the original problem both in an almost-sure sense and in a mean sense. The convergence rate is derived in terms of the objective function value and is shown to be  $\mathcal{O}(1/k^{(1/3-\epsilon)})$ , where  $\epsilon$  is an arbitrary small positive scalar. (ii) In deterministic regimes, we show that the algorithm displays a rate  $\mathcal{O}(1/k^{1-\epsilon})$ . We present numerical experiments performed on a large-scale text classification problem and compare IRS-LBFGS with standard SQN methods as well as first-order methods such as SAGA and IAG.

**Key words.** stochastic optimization, quasi-Newton, regularization, large scale optimization

**1. Introduction.** We consider the following stochastic optimization problem:

$$(SO) \quad \min_{x \in \mathbb{R}^n} f(x) \triangleq \mathbb{E}[F(x, \xi(\omega))],$$

where  $F : \mathbb{R}^n \times \mathbb{R}^d \rightarrow \mathbb{R}$  is a real-valued function, the random vector  $\xi$  is defined as  $\xi : \Omega \rightarrow \mathbb{R}^d$ ,  $(\Omega, \mathcal{F}, \mathbb{P})$  denotes the associated probability space, and the expectation  $\mathbb{E}[F(x, \xi)]$  is taken with respect to  $\mathbb{P}$ . Problem (SO) provides a formulation that can capture a wide range of applications in operations research, machine learning, statistics, and control to name a few (cf. [2, 3]). Significant progress in the resolution of (SO) has been made via Monte Carlo sampling techniques. Amongst such schemes,

stochastic approximation (SA) methods [22, 25] have proven particularly popular. The standard SA method, introduced by Robbins and Monro [25], for solving (SO), produces a sequence  $\{x_k\}$  using the following update rule:

$$(SA) \quad x_{k+1} := x_k - \gamma_k \nabla F(x_k, \xi_k) \quad \text{for } k \geq 0,$$

where  $x_0 \in \mathbb{R}^n$  is a randomly generated initial point,  $\gamma_k > 0$  denotes the step size, and  $\nabla F(x_k, \xi_k)$  denotes a sampled gradient of  $f$  with respect to  $x$  at  $x_k$ . SA schemes are characterized by several disadvantages, including a poorer rate of convergence (than their deterministic counterparts) and the detrimental impact of conditioning on their performance. In deterministic regimes, the BFGS method, named after Broyden, Fletcher, Goldfarb, and Shanno, is amongst the most popular quasi-Newton methods [6, 8], displaying a superlinear convergence rate without requiring second-order information. Addressing large-scale deterministic problems, the limited-memory variant of the BFGS method, denoted by L-BFGS, was developed and attains an  $R$ -linear convergence rate under strong convexity of the objective function (see [13, Theorem 6.1]). Recently, there has been a growing interest in applying stochastic quasi-Newton (SQN) methods for solving large-scale optimization and machine learning problems. In these methods,  $x_k$  is updated by the following rule:

$$(SQN) \quad x_{k+1} := x_k - \gamma_k H_k \nabla F(x_k, \xi_k) \quad \text{for } k \geq 0,$$

where  $H_k \succeq 0$  is an approximation of the inverse of the Hessian at iteration  $k$  that incorporates the curvature information of the objective function within the algorithm. The convergence of this class of algorithms can be derived under a careful choice of  $H_k$  and the step size sequence  $\{\gamma_k\}$ . In particular, the boundedness of the eigenvalues of  $H_k$  is an important factor in achieving global convergence in convex and nonconvex problems (cf. [1, 12]). In [27] the performance of SQN methods was found to be favorable in solving high dimensional problems. Mokhtari and Ribeiro [19] considered stochastic optimization problems with strongly convex objectives and developed a regularized BFGS method (RES) by updating  $H_k$  according to a modified version of the BFGS update rule to assure convergence. To address large-scale applications, limited-memory variants were employed to attain scalability in terms of the number of variables [3, 20]. Recent extensions have included an SQN method [30] for solving nonconvex stochastic optimization problems and a constant step size variance reduced SQN method [14] for smooth strongly convex problems characterized by a linear convergence rate. Finally, an incremental quasi-Newton (IQN) method with a local superlinear convergence rate has been recently developed for addressing the sum of a large number of strongly convex functions [18].

**Motivation.** In both the full and limited memory variants of the SQN methods in the literature [3, 18, 20], it has been uniformly assumed that the objective function is strongly convex. This assumption plays an important role in deriving the rate of convergence. However, in many applications, the objective function is not strongly convex but merely convex such as when considering the logistic regression function. While a lack of strong convexity might lead to slower convergence in practice, no rigorous support for the convergence rate is currently available in the literature of SQN methods. A simple remedy to address this challenge is to regularize the objective function with the term  $\frac{1}{2}\mu\|x\|^2$  and solve the approximate problem of the form  $\min_{x \in \mathbb{R}^n} f(x) + \frac{\mu}{2}\|x\|^2$ , where  $\mu > 0$  is the regularization parameter. Several challenges arise in applying this technique. A drawback of this technique is that the optimal solution to the regularized problem is not necessarily an optimal solution of

the original problem (SO). Yet, another challenge arises from the choice of  $\mu$ . While larger values of  $\mu$  may result in large deviations from the true optimal solution(s), choosing a small  $\mu$  leads to a deterioration of the constant factor in the convergence rate of the algorithm. This issue has been addressed to some extent with the help of averaging techniques. In particular, under mere convexity, most first-order methods admit convergence rate guarantees under averaging. For example, averaging SA schemes achieve a rate of  $\mathcal{O}(\frac{M}{\sqrt{k}})$ , where  $M$  is an upper bound on the norm of the subgradient (see [21, 22]). In the past few years, fast incremental gradient methods with improved rates of convergence have been developed [5, 9, 26, 29]. Of these, SAGA [5] with averaging addresses the merely convex case and achieves a sublinear convergence rate  $\mathcal{O}(\frac{N}{k})$ , where  $N$  denotes the number of blocks, while in the presence of strong convexity, nonaveraging variants of SAGA and IAG [9] admit a linear convergence rate assuming that the function satisfies some suitable smoothness conditions.

A crucial concern that plagues the aforementioned schemes is that the averaging technique has a detrimental impact on inducing sparsity. In the case of incremental methods such as SAGA and IAG, despite the fast convergence speed, the application of these methods is impaired by the excessive memory requirements. For standard SAGA and IAG, the memory requirements are  $\mathcal{O}(nN)$ . Accordingly, in this paper, our main goal lies in addressing such shortcomings in the absence of strong convexity and developing a first-order method equipped with a rate of convergence for the generated nonaveraged iterates.

**Related research on regularization.** In optimization, in order to obtain solutions with desirable properties, it is common to regularize the problem (SO) as follows:

$$(1) \quad \min_{x \in \mathbb{R}^n} f_\mu(x) := f(x) + \mu R(x),$$

where  $R : \mathbb{R}^n \rightarrow \mathbb{R}$  is a proper convex function and the scalar  $\mu > 0$  is the regularization parameter. The properties of the regularized problem and its relation to the original problem have been investigated by different researchers. Mangasarian and his colleagues appear among the first researchers who studied exact regularization of linear and nonlinear programs [15, 17]. A regularization is said to be *exact* when an optimal solution of (1), is also optimal for problem (SO) if  $\mu$  is small enough. Friedlander and Tseng [7] and Tseng and Yun [28] established the necessary and sufficient conditions of exact regularization for convex programs and derived error bounds for inexact regularized convex problems. In a similar vein, exact regularization of variational inequality problems has been studied in [4]. A challenging question is concerned about the choice of the regularization parameter  $\mu$ . A common approach to find an acceptable value for  $\mu$  is through a two-loop scheme where in the inner loop, problem (1) is solved for a fixed value of  $\mu$ , while  $\mu$  is tuned in the outer loop. The main drawback of this approach is that, in general, there is no guidance on the tuning rule for  $\mu$ . In addition, this approach is computationally inefficient. Furthermore, tuning rules may result in losing the desired properties of the sample path of the solutions to regularized problems. In this paper, we address this issue through employing an iterative single-loop algorithm where we update the regularization parameter  $\mu$  at each iteration of the scheme and reduce it iteratively to zero [10, 34].

**Contributions.** We consider stochastic optimization problems with nonstrongly convex objective functions with Lipschitz continuous but possibly unbounded gradient mappings. Our main contributions are as follows:

(i) *Asymptotic convergence:* We develop an iteratively regularized SQN method where the step size, regularization parameter, and the Hessian inverse approximation

denoted by  $H_k$  are updated iteratively. We assume that  $H_k$  satisfies a set of general assumptions on its eigenvalues and its dependency on the uncertainty. The asymptotic convergence of the method is established under a suitable choice of an error function. For the sequence of the iterates  $\{x_k\}$  produced by the algorithm, we obtain a set of suitable conditions on the step size and regularization sequences for which  $f(x_k)$  converges to the optimal objective value, i.e.,  $f^*$ , of (SO) both in an almost sure sense and in a mean sense. We also derive an upper bound for  $f(x_k) - f^*$ .

(ii) *Rate of convergence for regularized LBFGS methods:* To address large-scale stochastic optimization problems, motivated by our earlier work [33] on SQN methods for small-scale stochastic optimization problems with non-strongly convex objectives, we develop an iteratively regularized stochastic limited-memory BFGS scheme (see Algorithm 1). We show that under a careful choice of the update rules for the step size and regularization parameter, Algorithm 1 displays a convergence rate  $\mathcal{O}(k^{-(\frac{1}{3}-\epsilon)})$  in terms of the objective function value, where  $\epsilon$  is an arbitrary small positive scalar. Similar to standard stochastic LBFGS schemes, the memory requirement is independent of  $N$  and is  $\mathcal{O}(mn)$ , where  $m \ll n$  denote the memory parameter in the LBFGS scheme. In the deterministic case, we show that the convergence rate improves to  $\mathcal{O}(\frac{1}{k^{1-\epsilon}})$ . Both of these convergence rates appear to be new for the class of deterministic and SQN methods.

**Outline of the paper.** The rest of the paper is organized as follows. Section 2 presents the general framework of the proposed SQN algorithm and the sets of main assumptions. In section 3, we prove the asymptotic convergence of the iterates produced by the scheme in both an almost sure sense and a mean sense and derive a general error bound. In section 4, we develop an iteratively regularized stochastic LBFGS method (Algorithm 1) and derive its convergence rate. The rate analysis is also provided for the deterministic variant of this scheme. We then present the numerical experiments performed on a large-scale classification problem in section 5. The paper ends with some concluding remarks in section 6.

**Notation.** A vector  $x$  is assumed to be a column vector and  $x^T$  denotes its transpose, while  $\|x\|$  denotes the Euclidean vector norm, i.e.,  $\|x\| = \sqrt{x^T x}$ . We write a.s. as the abbreviation for “almost surely.” For a symmetric matrix  $B$ ,  $\lambda_{\min}(B)$  and  $\lambda_{\max}(B)$  denote the smallest and largest eigenvalues of  $B$ , respectively. We use  $\mathbb{E}[z]$  to denote the expectation of a random variable  $z$ . A function  $f : X \subseteq \mathbb{R}^n \rightarrow \mathbb{R}$  is said to be strongly convex with parameter  $\mu > 0$ , if  $f(y) \geq f(x) + \nabla f(x)^T(y-x) + \frac{\mu}{2}\|x-y\|^2$  for any  $x, y \in X$ . A mapping  $F : X \subseteq \mathbb{R}^n \rightarrow \mathbb{R}$  is said to be Lipschitz continuous with parameter  $L > 0$  if for any  $x, y \in X$ , we have  $\|F(x) - F(y)\| \leq L\|x-y\|$ . For a continuously differentiable function  $f$  with Lipschitz gradients with parameter  $L > 0$ , we have  $f(y) \leq f(x) + \nabla f(x)^T(y-x) + \frac{L}{2}\|x-y\|^2$  for any  $x, y \in X$ . For a vector  $x \in \mathbb{R}^n$  and a nonempty set  $X \subseteq \mathbb{R}^n$ , the Euclidean distance of  $x$  from  $X$  is denoted by  $dist(x, X)$ . We denote the optimal objective value of problem (SO) by  $f^*$  and the set of the optimal solutions by  $X^*$ .

**2. Outline of the SQN scheme.** In this section, we describe a general SQN scheme for solving problem (SO) and present the main assumptions. Let  $x_0 \in \mathbb{R}^n$  be an arbitrary initial point, and  $x_k$  be generated by the following recursive rule:

$$(IR-SQN) \quad x_{k+1} := x_k - \gamma_k H_k (\nabla F(x_k, \xi_k) + \mu_k(x_k - x_0)) \quad \text{for all } k \geq 0.$$

Here,  $\gamma_k$  and  $\mu_k$  are the step length and the regularization parameter, respectively.  $H_k \in \mathbb{R}^{n \times n}$  is a matrix that contains the curvature information of the objective function. The (IR-SQN) scheme can be seen as a regularized variant of the classical

stochastic SQN method. Here we regularize the gradient map by the term  $\mu_k(x_k - x_0)$  to induce the strong monotonicity property. In the absence of strong convexity of  $f$ , unlike the classical schemes where  $\mu_k$  is maintained fixed, we let  $\mu_k$  be updated and decreased to zero. Throughout, we let  $\mathcal{F}_k$  denote the history of the method up to time  $k$ , i.e.,  $\mathcal{F}_k \triangleq \{x_0, \xi_0, \xi_1, \dots, \xi_{k-1}\}$  for  $k \geq 1$ , and  $\mathcal{F}_0 \triangleq \{x_0\}$ .

*Assumption 1.* Consider problem (SO). Let the following hold:

- (a) The function  $f(x)$  is convex over  $\mathbb{R}^n$ .
- (b)  $f(x)$  is continuously differentiable with Lipschitz continuous gradients over  $\mathbb{R}^n$  with parameter  $L > 0$ .
- (c) The optimal solution set of the problem is nonempty.

Next, we state the assumptions on the random variable  $\xi$  and the properties of the stochastic estimator of the gradient mapping.

*Assumption 2* (random variable  $\xi$ ).

- (a) Vectors  $\xi_k \in \mathbb{R}^d$  are independent and identically distributed realizations of the random variable  $\xi$  for any  $k \geq 0$ .
- (b) The stochastic gradient mapping  $\nabla F(x, \xi)$  is an unbiased estimator of  $\nabla f(x)$ , i.e.,  $\mathbb{E}[\nabla F(x, \xi)] = \nabla f(x)$  for all  $x$ , and has a bounded variance, i.e., there exists a scalar  $\nu > 0$  such that  $\mathbb{E}[\|\nabla F(x, \xi) - \nabla f(x)\|^2] \leq \nu^2$  for all  $x \in \mathbb{R}^n$ .

The next assumption pertains to the properties of  $H_k$ .

*Assumption 3* (conditions on matrix  $H_k$ ). Let the following hold for all  $k \geq 0$ :

- (a) The matrix  $H_k \in \mathbb{R}^{n \times n}$  is  $\mathcal{F}_k$ -measurable, i.e.,  $\mathbb{E}[H_k | \mathcal{F}_k] = H_k$ .
- (b) Matrix  $H_k$  is symmetric and positive definite and satisfies the following condition: There exist positive scalars  $\lambda_{\min}, \lambda$  and scalar  $\alpha \leq 0$  such that

$$\lambda_{\min} \mathbf{I} \preceq H_k \preceq \lambda \mu_k^\alpha \mathbf{I} \quad \text{for all } k \geq 0,$$

where  $\mu_k$  is the regularization parameter in (IR-SQN).

Assumption 3 holds for the stochastic gradient method, where  $H_k$  is the identity matrix,  $\lambda_{\min} = \lambda = 1$ , and  $\alpha = 0$ . In the case of employing an appropriate LBFGS update rule that will be discussed in section 4, the maximum eigenvalue is obtained in terms of the regularization parameter.

**3. Convergence analysis.** In this section, we present the convergence analysis of the (IR-SQN) method. Our discussion starts by some preliminary definitions and properties. After obtaining a recursive error bound for the method in Lemma 3, we show convergence a.s. in Proposition 4, establish convergence in the mean, and derive an error bound in Proposition 5.

**DEFINITION 1** (regularized function and gradient mapping). *Consider the sequence  $\{\mu_k\}$  of positive scalars and the starting point of the algorithm (IR-SQN), i.e.,  $x_0$ . The regularized function  $f_k$  and its gradient are defined as follows for all  $k \geq 0$ :*

$$f_k(x) \triangleq f(x) + \frac{\mu_k}{2} \|x - x_0\|^2, \quad \nabla f_k(x) \triangleq \nabla f(x) + \mu_k(x - x_0).$$

In a similar way, we denote the regularized stochastic function  $F(x, \xi)$  and its gradient with  $F_k$  and  $\nabla F_k$  for any  $\xi$ , respectively.

**PROPERTY 1** (properties of a regularized function). *We have*

- (a)  $f_k$  is strongly convex with a parameter  $\mu_k$ ;
- (b)  $f_k$  has Lipschitzian gradients with parameter  $L + \mu_k$ ;

- (c)  $f_k$  has a unique minimizer over  $\mathbb{R}^n$ , denoted by  $x_k^*$ . Moreover, for any  $x \in \mathbb{R}^n$ ,
- $$2\mu_k(f_k(x) - f_k(x_k^*)) \leq \|\nabla f_k(x)\|^2 \leq 2(L + \mu_k)(f_k(x) - f_k(x_k^*)).$$

The existence and uniqueness of  $x_k^*$  in Property 1(c) is due to the strong convexity of the function  $f_k$  (see, for example, [24, section 1.3.2]), while the relation for the gradient is known to hold for a strongly convex function with a parameter  $\mu$  that also has Lipschitz gradients with a parameter  $L$  (see [24, Lemma 1, p. 23]). In the convergence analysis, we make use of the following result, which can be found in [24, Lemma 10, p. 49].

**LEMMA 2.** *Let  $\{v_k\}$  be a sequence of nonnegative random variables, where  $E[v_0] < \infty$ , and let  $\{\alpha_k\}$  and  $\{\beta_k\}$  be deterministic scalar sequences such that*

$$E[v_{k+1}|v_0, \dots, v_k] \leq (1 - \alpha_k)v_k + \beta_k \quad a.s. \text{ for all } k \geq 0,$$

where  $0 \leq \alpha_k \leq 1$ ,  $\beta_k \geq 0$ ,  $\sum_{k=0}^{\infty} \alpha_k = \infty$ ,  $\sum_{k=0}^{\infty} \beta_k < \infty$ , and  $\lim_{k \rightarrow \infty} \frac{\beta_k}{\alpha_k} = 0$ . Then,  $v_k \rightarrow 0$  a.s.

Throughout, we denote the stochastic error of the gradient estimator by

$$(2) \quad w_k \triangleq \nabla F(x_k, \xi_k) - \nabla f(x_k) \quad \text{for all } k \geq 0.$$

Note that under Assumption 2, from the definition of  $w_k$  in (2), we obtain  $E[w_k | \mathcal{F}_k] = 0$  and  $E[\|w_k\|^2 | \mathcal{F}_k] \leq \nu^2$ . The following result plays a key role in the convergence and rate analysis of the proposed schemes.

**LEMMA 3** (a recursive error bound). *Consider the (IR-SQN) method and suppose Assumptions 1, 2, and 3 hold. Also, assume  $\mu_k$  is a nonincreasing sequence and let*

$$(3) \quad \gamma_k \mu_k^{2\alpha} \leq \frac{\lambda_{\min}}{\lambda^2(L + \mu_0)} \quad \text{for all } k \geq 0.$$

Then, the following inequality holds for all  $k \geq 0$ :

$$(4) \quad \begin{aligned} E[f_{k+1}(x_{k+1}) | \mathcal{F}_k] - f^* &\leq (1 - \lambda_{\min}\mu_k\gamma_k)(f_k(x_k) - f^*) + \frac{\lambda_{\min} \text{dist}^2(x_0, X^*)}{2} \mu_k^2 \gamma_k \\ &\quad + \frac{(L + \mu_k)\lambda^2\nu^2}{2} \mu_k^{2\alpha} \gamma_k^2. \end{aligned}$$

*Proof.* The Lipschitzian property of  $\nabla f_k$  and the update rule (IR-SQN) imply that

$$\begin{aligned} f_k(x_{k+1}) &\leq f_k(x_k) + \nabla f_k(x_k)^T(x_{k+1} - x_k) + \frac{(L + \mu_k)}{2} \|x_{k+1} - x_k\|^2 \\ &= f_k(x_k) - \gamma_k \nabla f_k(x_k)^T H_k (\nabla F(x_k, \xi_k) + \mu_k(x_k - x_0)) \\ &\quad + \frac{(L + \mu_k)}{2} \gamma_k^2 \|H_k (\nabla F(x_k, \xi_k) + \mu_k(x_k - x_0))\|^2. \end{aligned}$$

Invoking the definition of the stochastic error  $w_k$  in (2) and Definition 1, we obtain

$$(5) \quad \begin{aligned} f_k(x_{k+1}) &\leq f_k(x_k) - \gamma_k \nabla f_k(x_k)^T H_k (\nabla f(x_k) + w_k + \mu_k(x_k - x_0)) \\ &\quad + \frac{(L + \mu_k)}{2} \gamma_k^2 \|H_k (\nabla f(x_k) + w_k + \mu_k(x_k - x_0))\|^2 \\ &= f_k(x_k) - \gamma_k \underbrace{\nabla f_k(x_k)^T H_k (\nabla f_k(x_k) + w_k)}_{\text{Term 1}} \\ &\quad + \frac{(L + \mu_k)}{2} \gamma_k^2 \underbrace{\|H_k (\nabla f_k(x_k) + w_k)\|^2}_{\text{Term 2}}, \end{aligned}$$

where in the last equation, we used the definition of  $f_k$ . Next, we estimate the conditional expectation of Terms 1 and 2. From Assumption 3, we have

$$\begin{aligned} \text{Term 1} &= \nabla f_k(x_k)^T H_k \nabla f_k(x_k) + \nabla f_k(x_k)^T H_k w_k \\ &\geq \lambda_{\min} \|\nabla f_k(x_k)\|^2 + \nabla f_k(x_k)^T H_k w_k. \end{aligned}$$

Taking expectations conditioned on  $\mathcal{F}_k$ , from the preceding inequality, we obtain

$$\begin{aligned} (6) \quad \mathbb{E}[\text{Term 1} | \mathcal{F}_k] &\geq \lambda_{\min} \|\nabla f_k(x_k)\|^2 + \mathbb{E}[\nabla f_k(x_k)^T H_k w_k | \mathcal{F}_k] \\ &= \lambda_{\min} \|\nabla f_k(x_k)\|^2 + \nabla f_k(x_k)^T H_k \mathbb{E}[w_k | \mathcal{F}_k] = \lambda_{\min} \|\nabla f_k(x_k)\|^2, \end{aligned}$$

where we recall that  $\mathbb{E}[w_k | \mathcal{F}_k] = 0$  and  $\mathbb{E}[H_k | \mathcal{F}_k] = H_k$ . Similarly, in Term 2, invoking Assumption 3(b), we may write

$$\begin{aligned} \text{Term 2} &= (\nabla f_k(x_k) + w_k)^T H_k^2 (\nabla f_k(x_k) + w_k) \leq (\lambda \mu_k^\alpha)^2 \|\nabla f_k(x_k) + w_k\|^2 \\ &= \lambda^2 \mu_k^{2\alpha} (\|\nabla f_k(x_k)\|^2 + \|w_k\|^2 + 2 \nabla f_k(x_k)^T w_k). \end{aligned}$$

Taking conditional expectations from the preceding inequality, and using Assumption 2, we obtain

$$\begin{aligned} \mathbb{E}[\text{Term 2} | \mathcal{F}_k] &\leq \lambda^2 \mu_k^{2\alpha} (\|\nabla f_k(x_k)\|^2 + \mathbb{E}[\|w_k\|^2 | \mathcal{F}_k] + 2 \nabla f_k(x_k)^T \mathbb{E}[w_k | \mathcal{F}_k]) \\ (7) \quad &\leq \lambda^2 \mu_k^{2\alpha} (\|\nabla f_k(x_k)\|^2 + \nu^2). \end{aligned}$$

Next, taking conditional expectations in (5), and using (6) and (7), we obtain

$$\begin{aligned} \mathbb{E}[f_k(x_{k+1}) | \mathcal{F}_k] &\leq f_k(x_k) - \gamma_k \lambda_{\min} \|\nabla f_k(x_k)\|^2 \\ &\quad + \lambda^2 \mu_k^{2\alpha} \frac{(L + \mu_k)}{2} \gamma_k^2 (\|\nabla f_k(x_k)\|^2 + \nu^2) \\ &\leq f_k(x_k) - \frac{\gamma_k \lambda_{\min}}{2} \|\nabla f_k(x_k)\|^2 \left( 2 - \frac{\lambda^2 \mu_k^{2\alpha} \gamma_k (L + \mu_k)}{\lambda_{\min}} \right) \\ &\quad + \lambda^2 \mu_k^{2\alpha} \frac{(L + \mu_k)}{2} \gamma_k^2 \nu^2. \end{aligned}$$

From the assumption that  $\gamma_k$  and  $\mu_k$  satisfy  $\gamma_k \mu_k^{2\alpha} \leq \frac{\lambda_{\min}}{\lambda^2 (L + \mu_0)}$  for any  $k \geq 0$  and that  $\mu_k$  is nonincreasing, we have  $\gamma_k \mu_k^{2\alpha} \leq \frac{\lambda_{\min}}{\lambda^2 (L + \mu_k)}$ . As a consequence, we get  $2 - \frac{\lambda^2 \mu_k^{2\alpha} \gamma_k (L + \mu_k)}{\lambda_{\min}} \geq 1$ . Therefore, from the preceding inequality, we obtain

$$\mathbb{E}[f_k(x_{k+1}) | \mathcal{F}_k] \leq f_k(x_k) - \frac{\gamma_k \lambda_{\min}}{2} \|\nabla f_k(x_k)\|^2 + \lambda^2 \mu_k^{2\alpha} \frac{(L + \mu_k)}{2} \gamma_k^2 \nu^2.$$

Employing Property 1(c), we have

$$\mathbb{E}[f_k(x_{k+1}) | \mathcal{F}_k] \leq f_k(x_k) - \lambda_{\min} \mu_k \gamma_k (f_k(x_k) - f_k(x_k^*)) + \lambda^2 \mu_k^{2\alpha} \frac{(L + \mu_k)}{2} \gamma_k^2 \nu^2.$$

Note that, since  $\mu_k$  is a nonincreasing sequence, Definition 1 implies that

$$\mathbb{E}[f_{k+1}(x_{k+1}) | \mathcal{F}_k] \leq \mathbb{E}[f_k(x_{k+1}) | \mathcal{F}_k].$$

Therefore, we obtain

$$(8) \quad \begin{aligned} \mathbb{E}[f_{k+1}(x_{k+1}) | \mathcal{F}_k] &\leq f_k(x_k) - \lambda_{\min} \mu_k \underbrace{\gamma_k (f_k(x_k) - f_k(x_k^*))}_{\text{Term 3}} + \lambda^2 \mu_k^{2\alpha} \frac{(L + \mu_k)}{2} \gamma_k^2 \nu^2. \end{aligned}$$

Next, we derive a lower bound for Term 3. Since  $x_k^*$  is the unique minimizer of  $f_k$ , we have  $f_k(x_k^*) \leq f_k(x^*)$ . Therefore, invoking Definition 1, for an arbitrary optimal solution  $x^* \in X^*$ , we have

$$f_k(x_k) - f_k(x_k^*) \geq f_k(x_k) - f_k(x^*) = f_k(x_k) - f^* - \frac{\mu_k}{2} \|x^* - x_0\|^2.$$

From the preceding relation and (8), we have

$$\begin{aligned} \mathbb{E}[f_{k+1}(x_{k+1}) \mid \mathcal{F}_k] &\leq f_k(x_k) - \lambda_{\min} \mu_k \gamma_k (f_k(x_k) - f^*) + \frac{\lambda_{\min} \|x^* - x_0\|^2}{2} \mu_k^2 \gamma_k \\ &\quad + \frac{(L + \mu_k) \lambda^2 \nu^2}{2} \mu_k^{2\alpha} \gamma_k^2. \end{aligned}$$

Since  $x^*$  is an arbitrary optimal solution, taking the minimum from the right-hand side of the preceding inequality over  $X^*$ , we can replace  $\|x^* - x_0\|$  by  $\text{dist}(x_0, X^*)$ . Then, subtracting  $f^*$  from both sides of this relation yields the desired inequality.  $\square$

Next, we show the convergence of the scheme. In order to apply Lemma 2 to inequality (4) and prove the almost sure convergence, we use the following definitions:

$$(9) \quad \begin{aligned} v_k &:= f_k(x_k) - f^*, \quad \alpha_k := \lambda_{\min} \gamma_k \mu_k, \\ \beta_k &:= \frac{\lambda_{\min} \text{dist}^2(x_0, X^*)}{2} \mu_k^2 \gamma_k + \frac{(L + \mu_k) \lambda^2 \nu^2}{2} \mu_k^{2\alpha} \gamma_k^2. \end{aligned}$$

To satisfy the conditions of Lemma 2, we identify a set of sufficient conditions on  $\{\gamma_k\}$  and  $\{\mu_k\}$  in the following assumption. Later in the subsequent sections, for each class of algorithms, we provide a set of sequences that meet these assumptions.

*Assumption 4* (conditions on sequences for convergence a.s.). *Let the sequences  $\{\gamma_k\}$  and  $\{\mu_k\}$  be positive and satisfy the following conditions:*

- (a)  $\lim_{k \rightarrow \infty} \gamma_k \mu_k^{2\alpha-1} = 0$ ;
- (b)  $\{\mu_k\}$  is nonincreasing and  $\mu_k \rightarrow 0$ ;
- (c)  $\lambda_{\min} \gamma_k \mu_k \leq 1$  for  $k \geq 0$ ;
- (d)  $\sum_{k=0}^{\infty} \gamma_k \mu_k = \infty$ ;
- (e)  $\sum_{k=0}^{\infty} \mu_k^2 \gamma_k < \infty$ ;
- (f)  $\sum_{k=0}^{\infty} \gamma_k^2 \mu_k^{2\alpha} < \infty$ .

**PROPOSITION 4** (almost sure convergence). *Consider the (IR-SQN) scheme. Suppose Assumptions 1, 2, 3, and 4 hold. Then,  $\lim_{k \rightarrow \infty} f(x_k) = f^*$  a.s.*

*Proof.* First, note that from Assumptions 4(a), (b), we have  $\lim_{k \rightarrow \infty} \gamma_k \mu_k^{2\alpha} = 0$ . Thus, there exists  $K \geq 1$  such that for any  $k \geq K$ , we have  $\gamma_k \mu_k^{2\alpha} \leq \frac{\lambda_{\min}}{\lambda^2(L+\mu_0)}$  implying that condition (3) of Lemma 3 holds for all  $k \geq K$ . Hence, relation (4) holds for any  $k \geq K$ . Next, we apply Lemma 2 to prove convergence of the (IR-SQN) scheme. Consider the definitions in (9) for any  $k \geq K$ . The nonnegativity of  $\alpha_k$  and  $\beta_k$  is implied by the definition and that  $\lambda_{\min}$ ,  $\gamma_k$ , and  $\mu_k$  are positive. From (4), we have

$$\mathbb{E}[v_{k+1} \mid \mathcal{F}_k] \leq (1 - \alpha_k)v_k + \beta_k \quad \text{for all } k \geq K.$$

Since  $f^* \leq f(x)$  for any  $x \in \mathbb{R}^n$ , we can write  $v_k = (f(x_k) - f^*) + \frac{\mu_k}{2} \|x_k - x_0\|^2 \geq 0$ . From Assumption 4(c), we obtain  $\alpha_k \leq 1$ . Also, from Assumption 4(d), we get  $\sum_{k=K}^{\infty} \alpha_k = \infty$ . Using Assumptions 4(b), (e), (f) and the definition of  $\beta_k$  in (9), for an arbitrary solution  $x^*$ , we may prove the summability of  $\beta_k$  as follows:

$$\sum_{k=K}^{\infty} \beta_k \leq \frac{\lambda_{\min} \text{dist}^2(x_0, X^*)}{2} \sum_{k=K}^{\infty} \mu_k^2 \gamma_k + \frac{(L + \mu_0) \lambda^2 \nu^2}{2} \sum_{k=K}^{\infty} \mu_k^{2\alpha} \gamma_k^2 < \infty.$$

Similarly, we can write

$$\lim_{k \rightarrow \infty} \frac{\beta_k}{\alpha_k} \leq \frac{\text{dist}^2(x_0, X^*)}{2} \lim_{k \rightarrow \infty} \mu_k + \frac{(L + \mu_0)\lambda^2\nu^2}{2} \lim_{k \rightarrow \infty} \mu_k^{2\alpha-1} \gamma_k = 0,$$

where the last equation is implied by Assumptions 4(a), (b). Therefore, all conditions of Lemma 2 hold (with an index shift) and we conclude that  $v_k := f_k(x_k) - f^*$  converges to 0 a.s. Let us define  $v'_k := f(x_k) - f^*$  and  $v''_k := \frac{\mu_k}{2} \|x_k - x_0\|^2$ , so that  $v_k = v'_k + v''_k$ . Since  $v'_k$  and  $v''_k$  are nonnegative, and  $v_k \rightarrow 0$  a.s., it follows that  $v'_k \rightarrow 0$  and  $v''_k \rightarrow 0$  a.s., implying that  $\lim_{k \rightarrow \infty} f(x_k) = f^*$  a.s.  $\square$

In the following, our goal is to state the assumptions on the sequences  $\{\gamma_k\}$  and  $\{\mu_k\}$  under which we can show the convergence in the mean.

*Assumption 5* (conditions on sequences for convergence in the mean). Let the sequences  $\{\gamma_k\}$  and  $\{\mu_k\}$  be positive and satisfy the following conditions:

- (a)  $\lim_{k \rightarrow \infty} \gamma_k \mu_k^{2\alpha-1} = 0$ ;
- (b)  $\{\mu_k\}$  is nonincreasing and  $\mu_k \rightarrow 0$ ;
- (c)  $\lambda_{\min} \gamma_k \mu_k \leq 1$  for  $k \geq 0$ ;
- (d) There exist  $K_0$  and  $0 < \beta < 1$  such that

$$\gamma_{k-1} \mu_{k-1}^{2\alpha-1} \leq \gamma_k \mu_k^{2\alpha-1} (1 + \beta \lambda_{\min} \gamma_k \mu_k) \quad \text{for all } k \geq K_0;$$

- (e) There exists a scalar  $\rho > 0$  such that  $\mu_k^{2-2\alpha} \leq \rho \gamma_k$  for all  $k \geq 0$ .

Next, we use Assumption 5 to establish the convergence in mean.

**PROPOSITION 5** (convergence in the mean). *Consider the (IR-SQN) scheme. Suppose Assumptions 1, 2, 3, and 5 hold. Then, there exists  $K \geq 1$  such that*

$$(10) \quad \mathbb{E}[f(x_{k+1})] - f^* \leq \theta \gamma_k \mu_k^{2\alpha-1} \quad \text{for all } k \geq K,$$

where  $f^*$  is the optimal value of the problem and

$$(11) \quad \theta := \max \left\{ \frac{\mathbb{E}[f_{K+1}(x_{K+1})] - f^*}{\gamma_K \mu_K^{2\alpha-1}}, \frac{\rho \lambda_{\min} \text{dist}^2(x_0, X^*) + (L + \mu_0)\lambda^2\nu^2}{2\lambda_{\min}(1 - \beta)} \right\}.$$

Moreover,  $\lim_{k \rightarrow \infty} \mathbb{E}[f(x_k)] = f^*$ .

*Proof.* Note that Assumptions 5(a), (b) imply that (4) holds for a large enough  $k$ , say after  $\hat{K}$ . Then, since the conditions of Lemma 3 are met (with an index shift), taking expectations on both sides of (4), we obtain for any  $k \geq \hat{K}$ ,

$$\begin{aligned} \mathbb{E}[f_{k+1}(x_{k+1}) - f^*] &\leq (1 - \lambda_{\min} \mu_k \gamma_k) \mathbb{E}[f_k(x_k) - f^*] + \frac{\lambda_{\min} \text{dist}^2(x_0, X^*)}{2} \mu_k^2 \gamma_k \\ &\quad + \frac{(L + \mu_0)\lambda^2\nu^2}{2} \mu_k^{2\alpha} \gamma_k^2. \end{aligned}$$

Using Assumption 5(e), we have  $\mu_k^2 \gamma_k \leq \rho \gamma_k^2 \mu_k^{2\alpha}$ . Thus, we obtain

$$(12) \quad \begin{aligned} \mathbb{E}[f_{k+1}(x_{k+1}) - f^*] &\leq (1 - \lambda_{\min} \mu_k \gamma_k) \mathbb{E}[f_k(x_k) - f^*] \\ &\quad + \left( \frac{\rho \lambda_{\min} \text{dist}^2(x_0, X^*) + (L + \mu_0)\lambda^2\nu^2}{2} \right) \mu_k^{2\alpha} \gamma_k^2. \end{aligned}$$

Let us define  $K \triangleq \max\{\hat{K}, K_0\}$ , where  $K_0$  is from Assumption 5(d). Using the preceding relation and by induction on  $k$ , we show the desired result. To show (10), we show the following relation first:

$$(13) \quad \mathbb{E}[f_{k+1}(x_{k+1})] - f^* \leq \theta \gamma_k \mu_k^{2\alpha-1} \quad \text{for all } k \geq K.$$

Note that (13) implies the relation (10) since we have  $\mathbb{E}[f(x_{k+1})] \leq \mathbb{E}[f_{k+1}(x_{k+1})]$ . First, we show that (13) holds for  $k = K$ . Consider the term  $\mathbb{E}[f_{K+1}(x_{K+1})] - f^*$ . Multiplying and dividing by  $\gamma_K \mu_K^{2\alpha-1}$ , we obtain

$$\mathbb{E}[f_{K+1}(x_{K+1})] - f^* = \left( \frac{\mathbb{E}[f_{K+1}(x_{K+1})] - f^*}{\gamma_K \mu_K^{2\alpha-1}} \right) \gamma_K \mu_K^{2\alpha-1} \leq \theta \gamma_K \mu_K^{2\alpha-1},$$

where the last inequality is obtained by invoking the definition of  $\theta$  in (11). This implies that (13) holds for  $k = K$ . Now assume that (13) holds for some  $k \geq K$ . We show that it also holds for  $k + 1$ . From the induction hypothesis and (12) we have

$$\begin{aligned} \mathbb{E}[f_{k+1}(x_{k+1}) - f^*] &\leq (1 - \lambda_{\min} \mu_k \gamma_k) \theta \gamma_{k-1} \mu_{k-1}^{2\alpha-1} \\ &\quad + \left( \frac{\rho \lambda_{\min} \text{dist}^2(x_0, X^*) + (L + \mu_0) \lambda^2 \nu^2}{2} \right) \mu_k^{2\alpha} \gamma_k^2. \end{aligned}$$

Using Assumption 5(d) we obtain

$$\begin{aligned} \mathbb{E}[f_{k+1}(x_{k+1}) - f^*] &\leq \theta \gamma_k \mu_k^{2\alpha-1} (1 - \lambda_{\min} \mu_k \gamma_k) (1 + \beta \lambda_{\min} \gamma_k \mu_k) \\ (14) \quad &\quad + \left( \frac{\rho \lambda_{\min} \text{dist}^2(x_0, X^*) + (L + \mu_0) \lambda^2 \nu^2}{2} \right) \mu_k^{2\alpha} \gamma_k^2. \end{aligned}$$

Next we find an upper bound for the term  $(1 - \lambda_{\min} \mu_k \gamma_k)(1 + \beta \lambda_{\min} \gamma_k \mu_k)$  as follows:

$$\begin{aligned} (1 - \lambda_{\min} \mu_k \gamma_k)(1 + \beta \lambda_{\min} \gamma_k \mu_k) &= 1 - \lambda_{\min} \mu_k \gamma_k + \beta \lambda_{\min} \mu_k \gamma_k - \beta \lambda_{\min}^2 \mu_k^2 \gamma_k^2 \\ &\leq 1 - (1 - \beta) \lambda_{\min} \mu_k \gamma_k. \end{aligned}$$

Combining this relation with (14), it follows that

$$\begin{aligned} \mathbb{E}[f_{k+1}(x_{k+1}) - f^*] &\leq \theta \gamma_k \mu_k^{2\alpha-1} - \theta \lambda_{\min} (1 - \beta) \mu_k^{2\alpha} \gamma_k^2 \\ &\quad + \left( \frac{\rho \lambda_{\min} \text{dist}^2(x_0, X^*) + (L + \mu_0) \lambda^2 \nu^2}{2} \right) \mu_k^{2\alpha} \gamma_k^2 \\ &= \theta \gamma_k \mu_k^{2\alpha-1} - \underbrace{\left( \theta \lambda_{\min} (1 - \beta) - \frac{\rho \lambda_{\min} \text{dist}^2(x_0, X^*) + (L + \mu_0) \lambda^2 \nu^2}{2} \right)}_{\text{Term 1}} \mu_k^{2\alpha} \gamma_k^2. \end{aligned}$$

Note that the definition of  $\theta$  in (11) implies that Term 1 is nonnegative. Therefore,

$$\mathbb{E}[f_{k+1}(x_{k+1}) - f^*] \leq \theta \gamma_k \mu_k^{2\alpha-1}.$$

Hence, the induction statement holds for  $k + 1$ . We conclude that (13) holds for all  $k \geq K$ . As a consequence, (10) holds for all  $k \geq K$  as well. To complete the proof, we need to show  $\lim_{k \rightarrow \infty} \mathbb{E}[f(x_k)] = f^*$ . This is an immediate result of (10) and Assumption 5(a).  $\square$

**4. Iteratively regularized stochastic and deterministic LBFGS methods.** In this section, our main goal is to develop an efficient update rule for matrix  $H_k$  of the (IR-SQN) scheme and establish a convergence rate result.

**4.1. Background.** Stochastic gradient methods are known to be sensitive to the choice of step sizes. In our prior work [16, 31, 32], we address this challenge in part by developing self-tuned step sizes under the strong convexity assumption. Another avenue to enhance the robustness of this scheme lies in incorporating curvature information of the objective function. A well-known updating rule for the matrix  $H_k$  that uses the curvature estimates is the BFGS update. The deterministic BFGS scheme achieves a superlinear convergence rate (cf. [23, Theorem 6.6]) outperforming the deterministic gradient/subgradient method. In the classical deterministic BFGS scheme, the curvature information is incorporated within the algorithm using two terms: The first term is the displacement factor  $s_k = x_{k+1} - x_k$ , while the other is the change in the gradient mapping,  $y_k = \nabla f(x_{k+1}) - \nabla f(x_k)$ , where  $\nabla f$  denotes the gradient mapping of the deterministic objective function  $f$ . To have a well-defined update rule, it is essential that at each iteration, the curvature condition  $s_k^T y_k > 0$  is satisfied. By maintaining this condition at each iteration, the positive definiteness of the approximate Hessian, denoted by  $B_k$ , is preserved. The BFGS update rule in the deterministic regime also ensures that  $B_k$  satisfies a secant equation given by  $B_{k+1}s_k = y_k$ , which ensures that the approximate Hessian maps  $s_k$  into  $y_k$ .

To address optimization problems in the stochastic regime, an update rule, namely RES, was developed for problem (SO) under the strong convexity assumption [19]. In problems with a large dimension (see [3] for some examples), the implementation of this scheme becomes challenging. This is because the computation of  $B_k$  and its inverse become expensive. Moreover, at each iteration, a matrix of size  $n \times n$  needs to be stored. To address these issues in large-scale optimization problems, limited-memory variants of a stochastic BFGS scheme, denoted by stochastic LBFGS, have been developed [3, 20]. The key idea in the LBFGS update rule is that instead of storing the full  $n \times n$  matrix at each iteration, a fixed number of vectors of size  $n$  are stored and used to update the approximate Hessian inverse.

**4.2. Outline of the stochastic LBFGS scheme.** The strong convexity property assumed in [3, 20] plays a key role in developing the LBFGS update rules and establishing the convergence. Note that in the absence of strong convexity, the curvature condition does not hold. To address this issue, a standard approach is to employ a damped variant of the BFGS update rule [23]. A drawback of this class of update rules is that there is no guarantee on the rate statements under such rules. Here, we resolve this issue through employing the properties of the regularized gradient map. This is carried out in (IR-SQN) by adding the regularization term  $\mu_k(x_k - x_0)$  to the stochastic gradient mapping  $\nabla F(x_k, \xi_k)$ . To maintain the curvature condition, we consider updating the matrix  $H_k$  and the parameter  $\mu_k$  in alternate steps. Keeping the regularization parameter constant in one iteration allows for maintaining the curvature condition. After updating  $H_k$ , in the subsequent iteration, we keep this matrix fixed and drop the value of the regularized parameter. Accordingly, the update rule for the regularization parameter  $\mu_k$  is based on the following general procedure:

$$(15) \quad \begin{cases} \mu_k := \mu_{k-1} & \text{if } k \text{ is odd,} \\ \mu_k < \mu_{k-1} & \text{otherwise.} \end{cases}$$

Note that we allow for updating the step size sequence at each iteration. We construct

the update rule in terms of the following two factors defined for any odd  $k \geq 1$ :

$$(16) \quad \begin{aligned} s_{\lceil k/2 \rceil} &:= x_k - x_{k-1}, \\ y_{\lceil k/2 \rceil} &:= \nabla F(x_k, \xi_{k-1}) - \nabla F(x_{k-1}, \xi_{k-1}) + \tau \mu_k^\delta s_{\lceil k/2 \rceil}, \end{aligned}$$

where  $\tau > 0$  and  $0 < \delta \leq 1$  are parameters to control the level of regularization in the matrix  $H_k$ . Here,  $\delta$  only controls the regularization for matrix  $H_k$ , but not that of the gradient direction. It is assumed that  $\delta > 0$  to ensure that the perturbation term  $\mu_k^\delta s_{\lceil k/2 \rceil} \rightarrow 0$ , as  $k \rightarrow \infty$ . The update policy for  $H_k$  is defined as follows:

$$(17) \quad H_k \triangleq \begin{cases} H_{k,m} & \text{if } k \text{ is odd,} \\ H_{k-1} & \text{otherwise,} \end{cases}$$

where  $m < n$  (in the large-scale settings,  $m \ll n$ ) is the memory parameter and represents the number of pairs  $(s_i, y_i)$  to be stored to estimate  $H_k$ . Matrix  $H_{k,m}$ , for any odd  $k \geq 2m-1$ , is updated using the following recursive formula:

$$(18) \quad H_{k,j} := \left( \mathbf{I} - \frac{y_i s_i^T}{y_i^T s_i} \right)^T H_{k,j-1} \left( \mathbf{I} - \frac{y_i s_i^T}{y_i^T s_i} \right) + \frac{s_i s_i^T}{y_i^T s_i}, \quad 1 \leq j \leq m,$$

where  $i \triangleq \lceil k/2 \rceil - (m-j)$  and we set  $H_{k,0} := \frac{s_{\lceil k/2 \rceil}^T y_{\lceil k/2 \rceil}}{y_{\lceil k/2 \rceil}^T y_{\lceil k/2 \rceil}} \mathbf{I}$ . Here, at odd iterations, matrix  $H_k$  is obtained recursively from  $H_{k,0}, H_{k,1}, \dots, H_{k,m-1}$ . Note that computation of  $H_k$  at an odd  $k$  needs  $m$  pairs of  $(s_i, y_i)$ . More precisely,  $H_k$  uses the following curvature information:  $\{(s_i, y_i) \mid i = \lceil k/2 \rceil - m + 1, \lceil k/2 \rceil - m + 2, \dots, \lceil k/2 \rceil\}$ . For convenience, in the first  $2m-2$  iterations, we let  $H_k$  be the identity matrix. This allows for collecting the first set of  $m$  pairs  $(s_i, y_i)$ , where  $i = 1, 2, \dots, m$ , that is used at iteration  $k := 2m-1$  to obtain  $H_{2m-1}$ . The main differences between update rule (18) and that of the standard SQN schemes [3, 20] are as follows: (i) The first distinction is with respect to the definition of  $y_i$  in (16). Here the term  $\mu_k^\delta s_{\lceil k/2 \rceil}$  compensates for the lack of strong monotonicity of the gradient mapping and aids in establishing the curvature condition. (ii) Second, instead of obtaining the pair  $(s_i, y_i)$  at every iteration, we evaluate these terms only at odd iterations to allow for updating the regularization parameter satisfying (15).

Implementation of this stochastic LBFGS scheme requires computing the term  $H_k \nabla F_k(x_k, \xi_k)$  at the  $k$ th iteration. This can be performed through a two-loop recursion with  $\mathcal{O}(mn)$  number of operations (see [23, Chap. 7, p. 178]). This will be shown for Algorithm 1 in Theorem 10(b).

In this section, we consider a stronger variant of Assumption 1 stated as follows.

*Assumption 6.*

- (a) The function  $F(x, \xi)$  is convex over  $\mathbb{R}^n$  for any  $\xi \in \Omega$ .
- (b) For any  $\xi \in \Omega$ ,  $F(\cdot, \xi)$  is continuously differentiable with Lipschitz continuous gradients over  $\mathbb{R}^n$  with parameter  $L_\xi > 0$ . Moreover,  $L := \sup_{\xi \in \Omega} L_\xi < \infty$ .
- (c) The optimal solution set  $X^*$  of problem (SO) is nonempty.

Next, in Lemma 7, we derive bounds on the eigenvalues of the matrix  $H_k$  and show that at iterations where  $H_k$  is updated, both the curvature condition and the secant equation hold. In the proof of Lemma 7, we will make use of the following result.

LEMMA 6. *Let  $0 < a_1 \leq a_2 \leq \dots \leq a_n$ , and  $P$  and  $S$  be positive scalars such that  $\sum_{i=1}^n a_i \leq S$  and  $\prod_{i=1}^n a_i \geq P$ . Then, we have  $a_1 \geq (n-1)!P/S^{n-1}$ .*

*Proof.* See Appendix 7.1 for the proof.  $\square$

LEMMA 7 (properties of update rule (17)–(18)). *Consider the (IR-SQN) method. Let  $H_k$  be given by the update rule (17)–(18), where  $s_i$  and  $y_i$  are defined in (16) and  $\mu_k$  is updated according to the procedure (15). Let Assumptions 6(a), (b) hold. Then, the following results hold:*

- (a) *For any odd  $k \geq 2m - 1$ , the curvature condition holds, i.e.,  $s_{\lceil k/2 \rceil}^T y_{\lceil k/2 \rceil} > 0$ .*
- (b) *For any odd  $k \geq 2m - 1$ , the secant equation holds, i.e.,  $H_k y_{\lceil k/2 \rceil} = s_{\lceil k/2 \rceil}$ .*
- (c) *For any  $k \geq 2m - 1$ ,  $H_k$  satisfies Assumption 3 with the following values:*

$$\lambda_{\min} = \frac{1}{(m+n)(L+\tau\mu_0^\delta)}, \quad \lambda = \frac{(m+n)^{n+m-1}(L+\tau\mu_0^\delta)^{n+m-1}}{(n-1)!\tau^{(n+m)}},$$

(19) and  $\alpha = -\delta(n+m)$ .

More precisely,  $H_k$  is symmetric,  $E[H_k | \mathcal{F}_k] = H_k$ , and

$$(20) \quad \frac{1}{(m+n)(L+\tau\mu_0^\delta)} \mathbf{I} \preceq H_k \preceq \frac{(m+n)^{n+m-1}(L+\tau\mu_0^\delta)^{n+m-1}}{(n-1)!(\tau\mu_k^\delta)^{(n+m)}} \mathbf{I}.$$

*Proof.* See Appendix 7.2 for the proof.  $\square$

In the following two lemmas, we provide update rules for the step size and the regularization parameter to ensure convergence in both an almost sure sense and mean sense for the proposed LBFGS scheme.

LEMMA 8 (feasible tuning sequences for convergence a.s. (Proposition 4)). *Let the sequences  $\gamma_k$  and  $\mu_k$  be given by the following rules:*

$$(21) \quad \gamma_k = \frac{\gamma_0}{(k+1)^a}, \quad \mu_k = \frac{2^b \mu_0}{(k+\kappa)^b},$$

where  $\kappa = 2$  if  $k$  is even and  $\kappa = 1$  otherwise,  $\gamma_0$  and  $\mu_0$  are positive scalars such that  $\gamma_0 \mu_0 \leq L(m+n)$ , and  $a$ ,  $b$ , and  $\delta \leq 1$  are positive scalars satisfying

$$\frac{a}{b} > 1 + 2\delta(n+m), \quad a+b \leq 1, \quad a+2b > 1, \quad \text{and} \quad a - \delta b(m+n) > 0.5.$$

Then,  $\gamma_k$  and  $\mu_k$  satisfy Assumption 4 with  $\lambda_{\min}$  and  $\alpha$  in (19) and  $\mu_k$  satisfies (15).

*Proof.* See Appendix 7.3 for the proof.  $\square$

Remark 1 (an example of feasible sequences). The conditions on parameters  $a$ ,  $b$ ,  $\gamma_0$ , and  $\mu_0$  in Lemma 8 hold for  $\gamma_0 = \mu_0 \leq \sqrt{L}$ ,  $a = \frac{5}{6}$  and  $b = \frac{1}{6}$ , and  $\delta = \frac{1}{m+n}$ .

LEMMA 9 (feasible tuning sequences for convergence in the mean (Proposition 5)). *Let the sequences  $\gamma_k$  and  $\mu_k$  be given by (21), where  $\gamma_0$  and  $\mu_0$  are positive scalars such that  $\gamma_0 \mu_0 \leq L(m+n)$ . Let  $0 < \delta \leq 1$ ,  $a > 0$ , and  $b > 0$  satisfying*

$$\frac{a}{b} > 1 + 2\delta(m+n), \quad a+b < 1, \quad \frac{a}{b} \leq 2(1 + \delta(m+n)).$$

Then,  $\mu_k$  satisfies (15) and  $\gamma_k$  and  $\mu_k$  satisfy Assumption 5 with any arbitrary  $0 < \beta < 1$ ,  $\rho \triangleq \gamma_0^{-1}(\mu_0 2^b)^{2+2\delta(m+n)}$ , and with  $\lambda_{\min}$  and  $\alpha$  given by (19).

*Proof.* See Appendix 7.4 for the proof.  $\square$

**4.3. An efficient implementation with rate analysis.** Algorithm 1 presents an efficient implementation of the proposed stochastic LBFGS scheme. Note that update rules for the step size and regularization parameter are specified in lines 2 and 4. Before presenting the complexity analysis in Theorem 10, we make some comments on the choice of parameter  $\tau$ .

*Remark 2.* As mentioned, the parameter  $\tau > 0$  in line 9 in Algorithm 1 is used to control the level of the iterative regularization employed in the computation of matrix  $H_k$ . Intuitively, it may seem that a small choice for  $\tau$  may reduce the distortion caused by the term  $\mu_k^\delta s_i$  in approximating the Hessian inverse and, consequently, improve the performance of the algorithm. However, this may not be always the case. To see this, first note that the relation (20) shows the dependency of eigenvalues of  $H_k$  on the choice of  $\tau$ . Recall that the relation (4) is a key assumption used in the convergence and rate analysis of the proposed method. It can be seen that when  $\tau \rightarrow 0$ , the

right-hand side of (4) will decrease to zero. This indicates that a small  $\tau$  enforces a small value for the term  $\gamma_0/\mu_0^{2\delta(n+m)}$ . For example, assuming a fixed value for  $\mu_0$ , this would lead to a small  $\gamma_0$ . This may have a negative impact on the performance of the algorithm. As such, it is not clear if a small  $\tau$  can be always beneficial. A closer look into this trade-off calls for a more detailed analysis of the finite-time performance of the algorithm, which is not the focus of our current work and remains as a future direction to our study.

In Theorem 10(a), we establish the convergence rate of Algorithm 1. Moreover, in Theorem 10(b), we show that the term  $H_k \nabla F_k(x_k, \xi_k)$  is computed efficiently using the LBFGS two-loop recursion in the algorithm with  $\mathcal{O}(mn)$  complexity per iteration.

**THEOREM 10** (rate analysis for Algorithm 1). *Consider Algorithm 1. The following statements hold:*

(a) *Suppose Assumptions 2 and 6 hold. Then, there exists  $K \geq 2m - 1$  such that*

$$\mathbb{E}[f(x_k)] - f^* \leq \left( \frac{\theta\gamma_0}{(\mu_0 \sqrt[3]{2})^{1-2\alpha}} \right) \frac{1}{k^{\frac{1}{3}-\epsilon}} \quad \text{for all } k > K,$$

where  $\theta$  is given by (11), and  $\lambda_{\min}$ ,  $\lambda$ , and  $\alpha$  are given by (19).

(b) *Let the scheme be at the  $k$ th iteration, where  $k \geq 2m - 1$ . Then, by the end of the LBFGS two-loop recursion, i.e., line 26 in Algorithm 1, we have*

$$(22) \quad r = H_k (\nabla F(x_k, \xi_k) + \mu_k(x_k - x_0)),$$

where  $H_k$  is defined by (17).

*Proof.* (a) First, we show that the conditions of Proposition 5 are satisfied. Assumption 1 holds as a consequence of Assumption 6. From Lemma 7(c), Assumption 3 holds for any  $k \geq 2m - 1$  as well. To show that Assumption 5 holds, we apply Lemma 9. We have

$$\frac{a}{b} = \frac{\frac{2}{3} - \epsilon + \frac{2\delta(n+m)}{3}}{1/3} = 2 - 3\epsilon + 2\delta(n+m) > 1 + 2\delta(m+n),$$

where we used  $\epsilon < \frac{1}{3}$ . Moreover, since  $\delta < \frac{1.5\epsilon}{n+m}$ , we have  $a+b = 1-\epsilon + \frac{2\delta(n+m)}{3} < 1$ . Also, from the values of  $a$  and  $b$  we have  $2b(1+\delta(m+n)) = a+\epsilon > a$ . Thus, the conditions of Lemma 9 hold. This implies that there exists  $K_0 > 0$  such that for any  $k \geq K_0$ , the sequences  $\gamma_k$  and  $\mu_k$  satisfy Assumption 5 with any arbitrary  $0 < \beta < 1$  and for  $\rho = \gamma_0^{-1}(\mu_0 2^b)^{2+2\delta(m+n)}$ , and with  $\lambda_{\min}$ ,  $\lambda$  and  $\alpha$  given by (19). Let us define  $K := \max\{K_0, 2m - 1\}$ . Since all conditions in Proposition 5 are met, from (10), (21), and by substituting values of  $a$ ,  $b$ , and  $\alpha$ , for any  $k \geq K$  we obtain

$$\begin{aligned} \mathbb{E}[f(x_{k+1})] - f^* &\leq \theta\gamma_{k-1}\mu_{k-1}^{2\alpha-1} = \frac{\theta\gamma_0(k+\kappa-1)^{(1-2\alpha)/3}}{(\mu_0 \sqrt[3]{2})^{1-2\alpha} k^{2/3-\epsilon-\frac{2}{3}\alpha}} \\ &\leq \frac{\theta\gamma_0(k+1)^{(1-2\alpha)/3}}{(\mu_0 \sqrt[3]{2})^{1-2\alpha} (k+1)^{2/3-\epsilon-\frac{2}{3}\alpha}} = \left( \frac{\theta\gamma_0}{(\mu_0 \sqrt[3]{2})^{1-2\alpha}} \right) \frac{1}{(k+1)^{\frac{1}{3}-\epsilon}}. \end{aligned}$$

Through a change of variable from  $k+1$  to  $k$ , we conclude the result.

(b) To show (22), it suffices to show that

$$r = \begin{cases} H_{k,m} (\nabla F(x_k, \xi_k) + \mu_k(x_k - x_0)) & \text{if } k \text{ is odd,} \\ H_{k-1,m} (\nabla F(x_k, \xi_k) + \mu_k(x_k - x_0)) & \text{otherwise,} \end{cases}$$

where  $H_{k,m}$  is defined by the recursion (18) for an odd  $k$ . First, consider the case that  $k \geq 2m - 1$  is an odd number. As such, at the  $k$ th iteration, from line 7, we have  $i := \lceil k/2 \rceil$ . For clarity of the presentation, throughout this proof, we use  $K$  (instead of  $i$ ), i.e.,  $K \triangleq \lceil k/2 \rceil$  and  $q_{K-t+1}$  is used to denote the value of the vector  $q \in \mathbb{R}^n$  after being updated at iteration  $t$  in line 21. Similarly, we use  $r_{t-K+m}$  to denote the value of the vector  $r \in \mathbb{R}^n$  after being updated at iteration  $t$  in line 25. Also, we use the following definitions:

$$\begin{aligned} q_0 &\triangleq \nabla F(x_k, \xi_k) + \mu_k(x_k - x_0), \quad r_0 \triangleq H_{k,0}q_m, \\ \rho_j &\triangleq \frac{1}{y_j^T s_j}, \text{ and } V_j \triangleq \mathbf{I} - \rho_j y_j s_j^T \quad \text{for all } j = K - (m-1), \dots, K. \end{aligned}$$

Consider relation (18). By applying this recursive relation repeatedly, we obtain

$$\begin{aligned} (23) \quad H_{k,m} &= \left( \prod_{j=1}^m V_{K-(m-j)} \right)^T H_{k,0} \left( \prod_{j=1}^m V_{K-(m-j)} \right) \\ &\quad + \rho_{K-m+1} \left( \prod_{j=2}^m V_{K-(m-j)} \right)^T s_{K-m+1} s_{K-m+1}^T \left( \prod_{j=2}^m V_{K-(m-j)} \right) \\ &\quad + \rho_{K-m+2} \left( \prod_{j=3}^m V_{K-(m-j)} \right)^T s_{K-m+2} s_{K-m+2}^T \left( \prod_{j=3}^m V_{K-(m-j)} \right) \\ &\quad + \dots \\ &\quad + \rho_{K-1} V_K^T s_{K-1} s_{K-1}^T V_K \\ &\quad + \rho_K s_K s_K^T. \end{aligned}$$

Next, we derive a formula for  $q_t$ . From lines 20–21 in the algorithm, we have

$$\begin{aligned} q_{K-t+1} &= q_{K-t} - \alpha_{K-t+1} y_t = q_{K-t} - \rho_t (s_t^T q_{K-t}) y_t = q_{K-t} - \rho_t (y_t s_t^T) q_{K-t} \\ &= (\mathbf{I} - \rho_t y_t s_t^T) q_{K-t} = V_t q_{K-t} \quad \text{for all } t = K, K-1, \dots, K-m+1. \end{aligned}$$

From the preceding relation, we obtain

$$(24) \quad q_\ell = \left( \prod_{j=m-\ell+1}^m V_{K-(m-j)} \right) q_0 \quad \text{for all } \ell = 1, 2, \dots, m.$$

From the update rule for  $\alpha_{i-t+1}$  in line 20, using the definition of  $\rho_t$ , and applying the previous relation, we have  $\alpha_1 = \rho_K s_K^T q_0$  and

$$(25) \quad \alpha_\ell = \rho_{K-\ell+1} s_{K-\ell+1}^T \left( \prod_{j=m-\ell+2}^m V_{K-(m-j)} \right) q_0 \quad \text{for all } \ell = 2, 3, \dots, m.$$

Multiplying both sides of (23) by  $q_0$  and employing (24) and (25), we obtain

$$(26) \quad H_{k,m}q_0 = \left( \prod_{j=1}^m V_{K-(m-j)} \right)^T H_{k,0}q_m + \left( \prod_{j=2}^m V_{K-(m-j)} \right)^T s_{K-m+1}\alpha_m \\ + \left( \prod_{j=3}^m V_{K-(m-j)} \right)^T s_{K-m+2}\alpha_{m-1} + \cdots + V_K^T s_{K-1}\alpha_2 + s_K\alpha_1.$$

Next, we derive a formula for  $r_t$ . From line 25 in the algorithm, we have

$$\begin{aligned} r_{t-K+m} &= r_{t-K+m-1} + (\alpha_{K-t+1} - \rho_t y_t^T r_{t-K+m-1}) s_t \\ &= r_{t-K+m-1} - \rho_t s_t y_t^T r_{t-K+m-1} + \alpha_{K-t+1} s_t \\ &= V_t^T r_{t-K+m-1} + \alpha_{K-t+1} s_t \quad \text{for all } t = K-m+1, \dots, K-1, K. \end{aligned}$$

Combining the preceding two relations, we obtain

$$r_\ell = V_{K-(m-\ell)}^T r_{\ell-1} + \alpha_{m-\ell+1} s_{K-(m-\ell)} \quad \text{for all } \ell = 1, 2, \dots, m.$$

Using the preceding equation repeatedly, we obtain

$$(27) \quad r_m = \left( \prod_{j=1}^m V_{K-(m-j)} \right)^T r_0 + \alpha_m \left( \prod_{j=2}^m V_{K-(m-j)} \right)^T s_{K-m+1} \\ + \alpha_{m-1} \left( \prod_{j=3}^m V_{K-(m-j)} \right)^T s_{K-m+2} + \cdots + \alpha_2 V_K^T s_{K-1} + \alpha_1 s_K.$$

From (27) and (26), and the definition of  $r_0$ , we obtain  $r_m = H_{k,m}q_0$ . Taking into account the definition of  $q_0$ , the desired result holds for any odd  $k \geq 2m-1$ . Now, consider the case where  $k \geq 2m-1$  is an even number. This implies that the “if” condition in line 6 is skipped and as such, the value of  $i$  is not updated from the iteration  $k-1$ , i.e.,  $i = \lceil (k-1)/2 \rceil$ . Consequently, the LBFGS two-loop recursion at an even  $k$  uses the following pairs:

$$\{(s_\ell, y_\ell) \mid \ell = \lceil (k-1)/2 \rceil - m + 1, \lceil (k-1)/2 \rceil - m + 2, \dots, \lceil (k-1)/2 \rceil\}.$$

Now, considering the definition (18) for  $k-1$ , the desired relation can be shown following the same steps discussed for the case the iteration number is odd.  $\square$

**4.4. Analysis of the deterministic case.** Our goal in the remainder of this section lies in establishing the convergence and rate statement for the deterministic LBFGS scheme. Consider the following regularized deterministic LBFGS method,

$$(\text{IR-LBFGS}) \quad x_{k+1} := x_k - \gamma_k H_k (\nabla f(x_k) + \mu_k (x_k - x_0)) \quad \text{for all } k \geq 0,$$

where  $H_k$  is given by the update rule (17),  $\mu_k$  is updated according to (15), and for an odd  $k \geq 1$  we set

$$(28) \quad \begin{aligned} s_{\lceil k/2 \rceil} &:= x_k - x_{k-1}, \\ y_{\lceil k/2 \rceil} &:= \nabla f(x_k) - \nabla f(x_{k-1}) + \tau \mu_k^\delta s_{\lceil k/2 \rceil}. \end{aligned}$$

**THEOREM 11** (convergence and rate analysis of iteratively regularized deterministic LBFGS (IR-LBFGS) method). *Let  $x_k$  be generated by the IR-LBFGS method. Suppose Assumption 1 holds. Let  $\lambda_{\min}$ ,  $\lambda$ , and  $\alpha$  be given by (19). Then the following hold.*

- (a) *Let  $\mu_k$  satisfy (15). If  $\gamma_k$  and  $\mu_k$  satisfy the following relation,*

$$(29) \quad \gamma_k \mu_k^{2\alpha} \leq \frac{\lambda_{\min}}{\lambda^2(L + \mu_0)} \quad \text{for all } k \geq 0,$$

*then, for any  $k \geq 0$ , we have*

$$(30) \quad f_{k+1}(x_{k+1}) - f^* \leq (1 - \lambda_{\min}\mu_k\gamma_k)(f_k(x_k) - f^*) + \frac{\lambda_{\min} \text{dist}^2(x_0, X^*)}{2} \mu_k^2 \gamma_k.$$

- (b) *Let  $\gamma_k$  and  $\mu_k$  be given by the update rule (21) where  $a, b > 0$  and  $0 < \delta \leq 1$  satisfy*

$$\frac{a}{b} > 2\delta(n+m) \quad a+b \leq 1, \quad a+2b > 1.$$

*Then,  $\lim_{k \rightarrow \infty} f(x_k) = f^*$ . Specifically, for  $a = \frac{4}{5}$ ,  $b = \frac{1}{5}$ , and  $\delta = \frac{1}{m+n}$ , this result holds.*

- (c) *Let  $\epsilon \in (0, 1)$  be an arbitrary small scalar. Let  $\gamma_k$  and  $\mu_k$  be given by the update rule (21) where  $a = \epsilon$ ,  $b = 1 - \epsilon$ . Also, assume  $\delta \in (0, \frac{\epsilon}{2(n+m)(1-\epsilon)})$ . Let  $\gamma_0$  and  $\mu_0$  satisfy the following condition:*

$$(31) \quad \gamma_0 \mu_0 \geq (n+m)(L + \tau \mu_0^\delta).$$

*Then, there exists  $K$  such that*

$$(32) \quad f(x_k) - f^* \leq \frac{\Gamma}{(k+1)^{1-\epsilon}} \quad \text{for all } k \geq K,$$

*where  $\Gamma \triangleq \max\{(K+1)^{1-\epsilon}(f_K(x_K) - f^*), \frac{\lambda_{\min}\gamma_0\mu_0^2 \text{dist}^2(x_0, X^*)}{4^a(\lambda_{\min}\gamma_0\mu_0 - b)}\}$ .*

*Proof.* (a) The conditions of Lemma 7 are met indicating that Assumption 7 holds. Assumption 2 is clearly met with  $\nu = 0$  as the problem is deterministic. Therefore, all of the conditions of Lemma 3 are satisfied and thus (4) holds. Substituting  $\nu = 0$  in (4) and eliminating the expectation operator yields the desired inequality.

- (b) First, we show that (30) holds. We can write

$$\gamma_k \mu_k^{2\alpha} = \frac{\gamma_0}{(2^b \mu_0)^{-2\alpha}} (k+1)^{-a} (k+\kappa)^{-2\alpha b} \leq \frac{\gamma_0}{(2^b \mu_0)^{-2\alpha}} (k+1)^{-a-2\alpha b}.$$

Note that the assumption that  $a > 2b\delta(n+m)$ , implies that  $-a-2ab < 0$ . Therefore,  $\gamma_k \mu_k^{2\alpha} \rightarrow 0$  showing that there exists  $K_0$  such that for any  $k \geq K_0$ , (30) holds. We apply Lemma 2 to the inequality (30) by setting

$$\alpha_k := \lambda_{\min}\gamma_0\mu_0, \quad \beta_k := \frac{\lambda_{\min} \text{dist}^2(x_0, X^*)}{2} \mu_k^2 \gamma_k, \quad v_k := f_k(x_k) - f^*.$$

From  $a+b \leq 1$ , we have  $\sum_{k=0}^{\infty} \alpha_k = \infty$ . Also,  $a+2b > 1$  indicates that  $\sum_{k=0}^{\infty} \beta_k < \infty$ . Since all conditions of Lemma 2 are met, we have  $f_k(x_k) \rightarrow f^*$ . Recalling Definition 1, this implies that  $f(x_k) \rightarrow f^*$ .

(c) First, we show that by the given update rules for  $\gamma_k$  and  $\mu_k$ , relation (30) holds. Note that  $\alpha = -\delta(n + m)$ . Therefore, we can write

$$\begin{aligned} \gamma_k \mu_k^{2\alpha} &= \frac{\gamma_0(k + \kappa)^{2(m+n)\delta b}}{(\mu_0 2^b)^{2(m+n)\delta} (k + 1)^a} \leq \frac{\gamma_0(k + 2)^{2(m+n)\delta b}}{(\mu_0 2^b)^{2(m+n)\delta} (k + 1)^a} \\ (33) \quad &= \frac{\gamma_0(1 + \frac{1}{k+1})^{2(m+n)\delta b}}{(\mu_0 2^b)^{2(m+n)\delta} (k + 1)^{a-2(m+n)\delta b}}. \end{aligned}$$

Using the condition on  $\delta$ , we have  $a - 2(m + n)b\delta = \epsilon - 2(1 - \epsilon)\delta(m + n) > 0$ . Thus, relation (33) indicates that there exists  $K_1$  such that for any  $k \geq K_1$ , (30) holds. Besides, since  $a$  and  $b$  are positive, there exists  $K_2$  such that for any  $k \geq K_2$ , we have  $(1 - \lambda_{\min} \gamma_k \mu_k) > 0$ . Let us now define  $K := \max\{K_1, K_2, 2m - 1\}$ . Next, we use induction on  $k$  to show (32). For  $k = K$ , it clearly holds. Let us assume (32) holds for  $k > K$ . Let  $e_k$  denote  $f_k(x_k) - f^*$ . From (30) and the update rules of  $\gamma_k$  and  $\mu_k$  we can write

$$\begin{aligned} e_k &\leq \left(1 - \frac{\lambda_{\min} \gamma_0 \mu_0 2^b}{k^a (k + \kappa - 1)^b}\right) e_{k-1} + \frac{\lambda_{\min} \text{dist}^2(x_0, X^*) \gamma_0 \mu_0^2 2^{2b-1}}{k^a (k + \kappa - 1)^{2b}} \\ &\leq \left(1 - \frac{\lambda_{\min} \gamma_0 \mu_0 2^b}{k^a (k + 1)^b}\right) e_{k-1} + \frac{\lambda_{\min} \text{dist}^2(x_0, X^*) \gamma_0 \mu_0^2 2^{2b-1}}{k^{a+2b}} \\ (34) \quad &\leq \left(1 - \frac{\lambda_{\min} \gamma_0 \mu_0}{k}\right) e_{k-1} + \frac{\lambda_{\min} \text{dist}^2(x_0, X^*) \gamma_0 \mu_0^2 2^{2b-1}}{k^{a+2b}}, \end{aligned}$$

where  $\kappa$  is defined in (21), and the last inequality is implied by  $\frac{k^a (k+1)^b}{k^{a+b}} \leq 2^b$  for  $k \geq 1$ . Note that since  $k \geq K_2$ , the term  $(1 - \frac{\lambda_{\min} \gamma_0 \mu_0}{k^{a+b}})$  in (34) is nonnegative. Therefore, we can replace  $e_{k-1}$  by its upper bound  $\frac{\Gamma}{k^b}$  in (34). Doing so and noticing that  $a + b = 1$ , we obtain

$$(35) \quad e_k \leq \left(1 - \frac{C_1}{k}\right) \frac{\Gamma}{k^b} + \frac{C_2}{k^{b+1}},$$

where we define  $C_1 \triangleq \lambda_{\min} \gamma_0 \mu_0$  and  $C_2 \triangleq \lambda_{\min} \text{dist}^2(x_0, X^*) \gamma_0 \mu_0^2 2^{2b-1}$ . Using (35), to show that  $e_k \leq \frac{\Gamma}{(k+1)^{1-a}}$ , it is enough to show that

$$\Gamma \left( \frac{1}{k^b} - \frac{1}{(k+1)^b} \right) \leq \frac{C_1 \Gamma - C_2}{k^{b+1}}.$$

Rearranging the terms, we need to verify that  $\Gamma \geq \frac{C_2}{C_1 - C_3}$  and  $C_3 < C_1$ , where  $C_3$  is an upper bound on  $\sup_{k \geq 1} \{k^{b+1} (\frac{1}{k^b} - \frac{1}{(k+1)^b})\}$ . We claim that  $C_3 := b$  is a feasible choice. To prove this, we need to show that  $k^{b+1} (\frac{1}{k^b} - \frac{1}{(k+1)^b}) \leq b$  or, equivalently,

$$\left(1 - \frac{1}{k+1}\right)^b \geq 1 - \frac{b}{k} \quad \text{for all } k \geq 1.$$

Consider the function  $g(x) := (1 - \frac{1}{1+x})^b + \frac{b}{x} - 1$  for  $x \geq 1$ . We have

$$g'(x) = \frac{b}{(1+x)^2} \left(1 - \frac{1}{1+x}\right)^{1-b} - \frac{b}{x^2} = \frac{b}{(1+x)^2} \left( \left(\frac{x+1}{x}\right)^{1-b} - \left(\frac{x+1}{x}\right)^2 \right) \leq 0$$

due to  $0 < b < 1$ . Hence,  $g$  is nonincreasing implying it suffices to show  $g(1) \geq 0$ , i.e.,  $2^b(1-b) \leq 1$ . Let us define  $h(x) := 2^x(1-x)$  for  $0 < x < 1$ . We have  $h'(x) = 2^x(\ln(2)(1-x) - 1)$ . This indicates that  $h'(x) < 0$  over  $x \in (0, 1)$ , implying that  $h(b) \leq h(0) = 1$ . Hence, we conclude that  $C_3 := b$  is a feasible choice. To show  $C_3 < C_1$  holds, we need to verify  $C_1 > b$ . This is true due to (31). To complete the proof we need to show  $\Gamma \geq \frac{C_2}{C_1-b}$ . This holds from the definition of  $\Gamma$ .  $\square$

**5. Numerical experiments.** In this section, we present the implementation results of Algorithm 1 on a classification application. The Reuters Corpus Volume I (RCV1) data set [11] is a collection of newswire stories produced by Reuters. After the tokenization process, each article is converted to a sparse binary vector, in that 1 denotes the existence and 0 denotes nonexistence of a token in the corresponding article. We consider a subset of the data with  $N = 100,000$  articles and  $n = 138,921$  tokens. The articles are categorized into different hierarchical groups. Here we focus our attention on the binary classification of the articles with respect to the Markets class. We consider the logistic regression loss minimization problem given as follows:

$$(LRM) \quad \min_{x \in \mathbb{R}^n} f(x) := \frac{1}{N} \sum_{i=1}^N \ln(1 + \exp(-u_i^T x v_i)),$$

where  $u_i \in \mathbb{R}^n$  is the input binary vector associated with article  $i$  and  $v_i \in \{-1, 1\}$  denotes the class of the  $i$ th article. We run three experiments. Of these, in section 5.1, we compare the performance of Algorithm 1 (with  $\tau = 1$ ) with that of standard SQN methods. In sections 5.2 and 5.3, we provide comparisons of Algorithm 1 with SAGA [5] and with IAG [9] applied to regularized problems, respectively.

**5.1. Comparison with standard SQN schemes.** To solve problem (LRM), the standard LBFGS methods in [3, 20] solve an approximate problem of the form

$$(Regularized LRM) \quad \min_{x \in \mathbb{R}^n} f(x) := \frac{1}{N} \sum_{i=1}^N \ln(1 + \exp(-u_i^T x v_i)) + \frac{\eta}{2} \|x\|^2,$$

where  $\eta > 0$  is an arbitrary regularization parameter. To perform the first experiment, we consider comparison of Algorithm 1 with three variants of the standard regularized stochastic LBFGS schemes, all denoted by RS-LBFGS (see Figure 1). In RS-LBFGS schemes, we use the step size of the form  $\gamma_k = \frac{\gamma_0}{k+1}$  and drop  $\eta$  at epochs of 400 iterations using a decay factor denoted by  $\rho \in (0, 1]$ . Of these, in the first scheme, we assume  $\rho = 1$ , meaning that  $\eta$  is kept constant throughout the implementation of the SQN scheme. In the second scheme, we use  $\rho = 0.5$ . This means, for example, after every 400 iterations, we set  $\eta := 0.5\eta$ . In the third scheme, we use  $\rho = 0.3$ . We let  $\gamma_0 \in \{10, 0.5, 0.1\}$ ,  $\eta_0 \in \{1, 0.5, 0.01\}$ ,  $m \in \{2, 5\}$ ,  $N = 10^4$ , and  $x_0$  be the origin. In all cases, we use five sample paths to calculate the average value of the objective function in (LRM).

**Insights.** We observe that Algorithm 1 performs uniformly better than the three variants of the standard SQN scheme under different tuning rules for the regularization parameter. This suggests that for merely convex stochastic optimization, SQN schemes using the tuning rules for the step size and regularization parameter given as  $\gamma_k \approx 1/\sqrt[3]{k^2}$  and  $\mu_k \approx 1/\sqrt[3]{k}$  have a faster convergence speed.

**5.2. Comparison with SAGA on merely convex problems.** Recall that in addressing the finite-sum minimization problems with merely convex objectives,

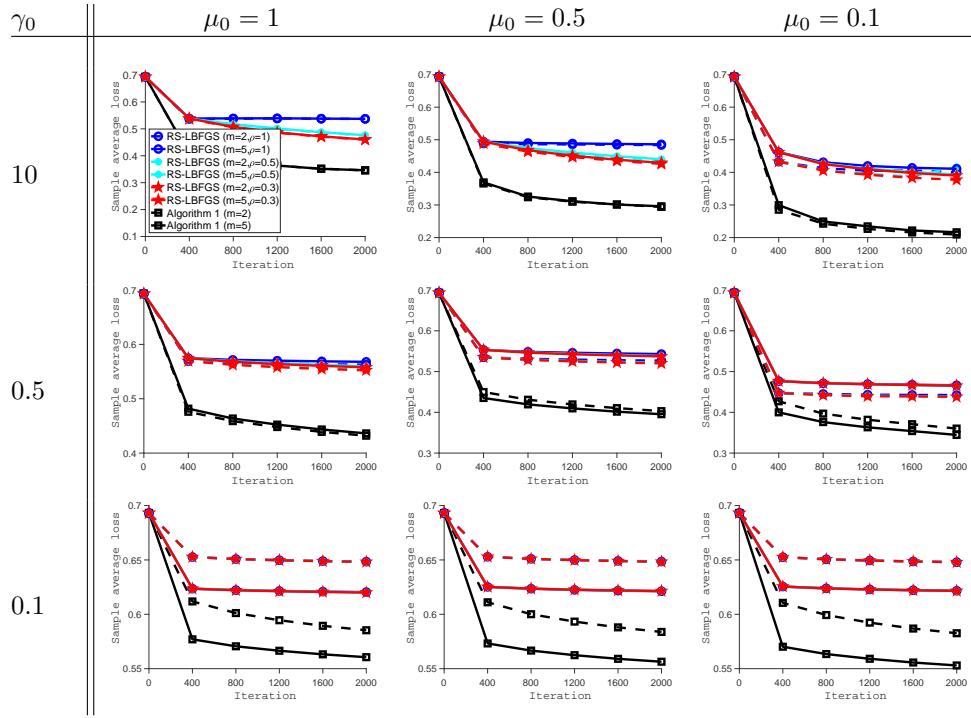

FIG. 1. Algorithm 1 versus stochastic LBFGS under constant regularization (i.e.,  $\rho = 1$ ), and under piecewise constant regularization (i.e.,  $\rho = 0.5, 0.3$ ), where  $\rho$  is the decay ratio of the regularization parameter at each epoch of 400 iterations.

employing averaging and under a constant step size, SAGA admits a sublinear convergence rate of  $\mathcal{O}(\frac{N}{k})$  [5]. The simulation results are provided in Figure 2. These results include different sample sizes, i.e.,  $N \in \{10^3, 10^4, 10^5\}$ , different initial conditions for SAGA, and different choices of the step sizes and the initial regularization parameter for Algorithm 1. SAGA uses the evaluation of the gradient map of the component functions at the starting point. Here, we use three different values for the evaluated gradient maps at the starting point, i.e., the origin, to study the sensitivity of SAGA with respect to the initial conditions. Of these, in initial condition 3, we use the exact value of the gradient maps, while in initial condition 2, we perturb values of the gradient maps. This perturbation is increased in initial condition 1.

**Insights.** From Figure 2, we observe that Algorithm 1 competes well with SAGA. We discuss the comparisons as follows: (i) A computational burden in implementation of SAGA is the memory requirement of this scheme. Generally speaking, SAGA requires storing a matrix of  $\mathcal{O}(Nn)$  at each iteration. Exceptions include the case where the objective function is in terms of a linear regression model function (e.g., in (LRM)). This is in contrast with Algorithm 1 where the memory requirement is  $\mathcal{O}(mn)$ . (ii) As expected, the performance of SAGA deteriorates when the sample size increases. However, the performance of Algorithm 1 seems to be more robust with respect to the increase in the sample size. (iii) The performance of SAGA seems to be moderately sensitive to the initial conditions.

**5.3. Comparison with IAG.** Recall that in solving finite-sum minimization problems with  $\mu$ -strongly convex objectives, using a constant step size, (nonaveraging)

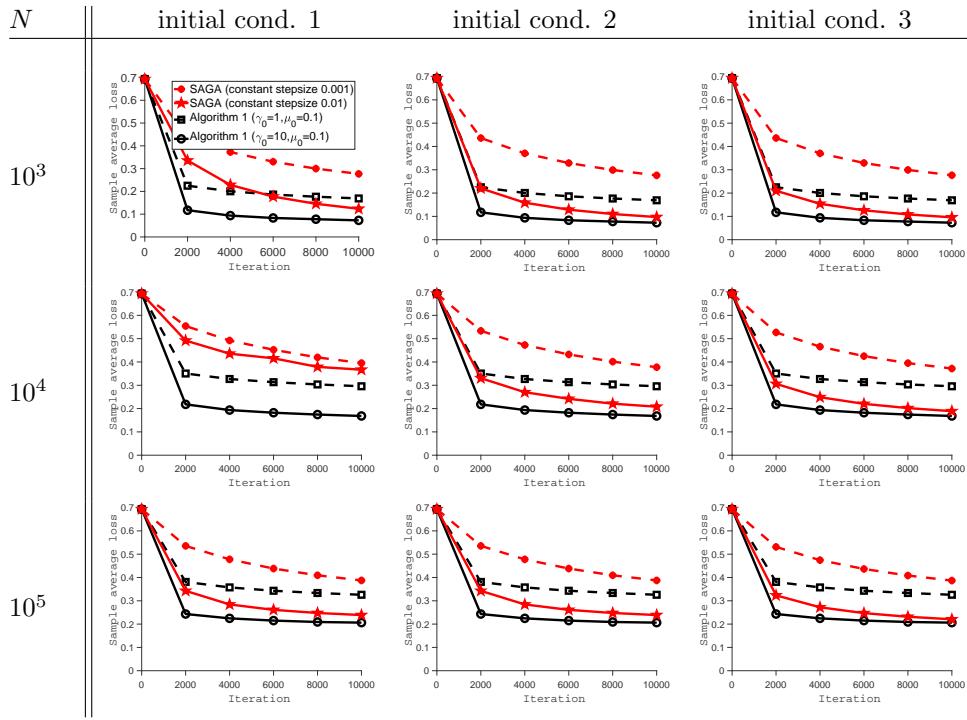

FIG. 2. Algorithm 1 versus SAGA (with averaging) with different choices of constant step size, different sample sizes, and different initial value of the gradient of component functions.

IAG admits a linear convergence rate of  $\mathcal{O}((1 - (\mu/N)^2)^{2k})$ , where  $N$  is the number of component functions (cf. [9]). Accordingly, to do the numerical comparisons with IAG, we regularize problem (LRM) with a constant  $\mu_{IAG} > 0$ . Figure 3 shows the simulation results for different choices of  $\mu_{IAG}$ ,  $N$ , IAG step size, and the initial step size and regularization parameter of Algorithm 1.

**Insights.** (i) Due to the excessive memory requirements of  $\mathcal{O}(nN)$  associated with IAG, such a scheme becomes challenging to implement when  $n$  becomes large as in this case where  $n = 138,921$ . Consequently, we use a sample size  $N \in \{1000, 2000, 5000\}$ . However, Algorithm 1 only requires memory of  $\mathcal{O}(nm)$ , allowing for implementations with large values of  $N$ . (ii) Similarly to SAGA, the performance of IAG is deteriorated when the sample size increases. However, the performance of Algorithm 1 seems to be more robust with changes in the sample size. (iii) For each fixed value of  $N$ , despite the change in the value of  $\mu_{IAG}$ , the performance of IAG in terms of the true objective function in (LRM) does not necessarily improve. Importantly, this observation suggests that in the standard regularization approach, tuning the regularization parameter could be computationally expensive.

**6. Concluding remarks.** We consider SQN methods for solving large-scale stochastic optimization problems with smooth but unbounded gradients. Much of the past research on convergence rates of these algorithms relies on the strong convexity of the objective function. We employ an iteratively regularized scheme where the regularization parameter is updated iteratively within the algorithm. We establish the convergence in an almost sure sense and a mean sense. Moreover, we prove that the sequence of iterates generated by the proposed stochastic LBFGS algorithm con-

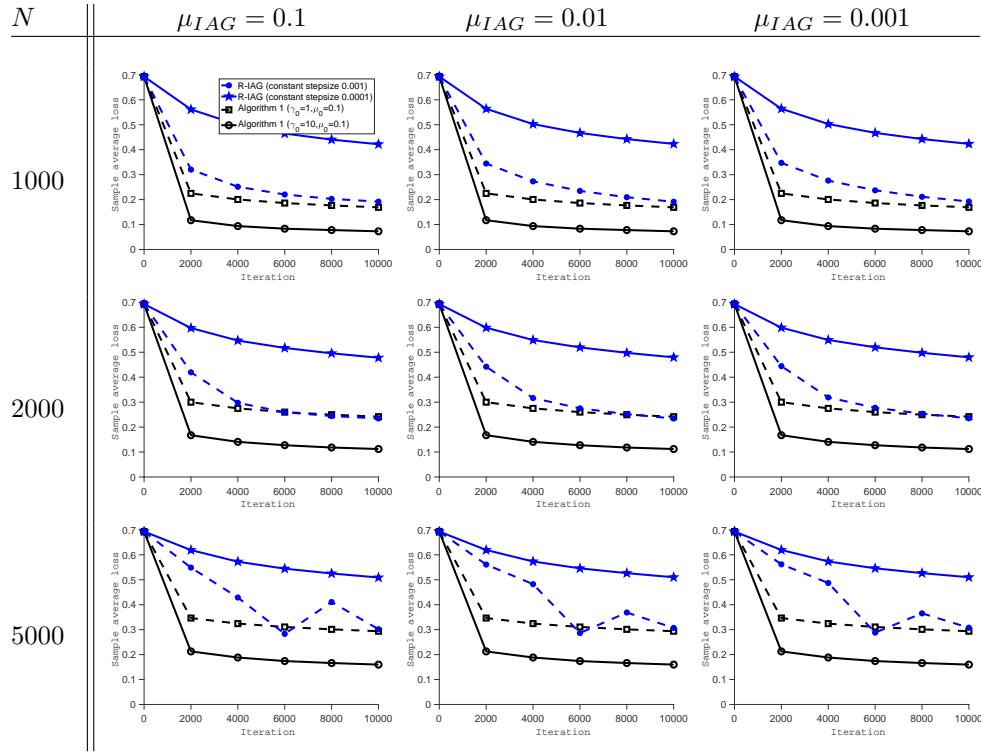

FIG. 3. Algorithm 1 versus regularized IAG (nonaveraging) with different choices of the regularization parameter, different choices of the step size, and different sample sizes.

verges to an optimal solution at the rate  $\mathcal{O}(\frac{1}{k^{1/3-\epsilon}})$  for an arbitrary small  $\epsilon > 0$ . The deterministic variant of this algorithm achieves the rate  $\mathcal{O}(\frac{1}{k^{1-\epsilon}})$ . The numerical experiments performed on a large-scale classification problem indicate that the proposed LBFGS scheme performs well compared to methods such as standard SQN schemes, and other first-order schemes such as SAGA and IAG.

## 7. Appendix.

### 7.1. Proof of Lemma 6.

From  $0 < a_1 \leq \dots \leq a_n$ , we can write

$$(n - (i - 1))a_i \leq \sum_{j=1}^n a_j \quad \text{for all } i \in \{1, \dots, n\}.$$

Invoking  $\sum_{i=1}^n a_i \leq S$ , we obtain  $a_i \leq \frac{S}{n-(i-1)}$  for all  $i \in \{1, \dots, n\}$ . From the preceding relation and that  $\prod_{j=1}^n a_j \geq P$ , we can obtain  $a_1 \geq (n-1)!P/S^{n-1}$ .

### 7.2. Proof of Lemma 7.

*Proof.* Throughout, we let  $\lambda_{k,\min}$ ,  $\lambda_{k,\max}$ , and  $B_k$  denote the minimum eigenvalue, maximum eigenvalue, and inverse of matrix  $H_k$  in (18), respectively. It can be seen, by induction on  $k$ , that  $H_k$  is symmetric and  $\mathcal{F}_k$  measurable. We use induction on odd values of  $k \geq 2m - 1$  to show that parts (a), (b), and (c) hold. Suppose  $k \geq 2m - 1$  is odd and for any odd  $t < k$ , we have  $s_{\lceil t/2 \rceil}^T y_{\lceil t/2 \rceil} > 0$ ,  $H_t y_{\lceil t/2 \rceil} = s_{\lceil t/2 \rceil}$ , and (20) for  $t$ . We show that these statements also hold for  $k$  as well. First, we show that the

curvature condition holds. We can write

$$\begin{aligned} s_{\lceil k/2 \rceil}^T y_{\lceil k/2 \rceil} &= (x_k - x_{k-1})^T (\nabla F(x_k, \xi_{k-1}) - \nabla F(x_{k-1}, \xi_{k-1}) + \tau \mu_k^\delta (x_k - x_{k-1})) \\ &= (x_k - x_{k-1})^T (\nabla F(x_k, \xi_{k-1}) - \nabla F(x_{k-1}, \xi_{k-1})) + \tau \mu_k^\delta \|x_k - x_{k-1}\|^2 \\ &\geq \tau \mu_k^\delta \|x_k - x_{k-1}\|^2, \end{aligned}$$

where the inequality follows from the monotonicity of the gradient map  $\nabla F(\cdot, \xi)$ . Next, we show that  $\|x_k - x_{k-1}\|^2 > 0$ . From the induction hypothesis and that  $k-2$  is odd,  $H_{k-2}$  is positive definite. Moreover, from the update rule (17) and that  $k-2$  is odd, we have  $H_{k-1} = H_{k-2}$ . Therefore,  $H_{k-1}$  is also positive definite. Without loss of generality, we assume  $\nabla F(x_{k-1}, \xi_{k-1}) + \mu_{k-1}(x_{k-1} - x_0) \neq 0$ .<sup>1</sup> Since  $H_{k-1}$  is positive definite, we have

$$H_{k-1} (\nabla F(x_{k-1}, \xi_{k-1}) + \mu_{k-1}(x_{k-1} - x_0)) \neq 0,$$

implying that  $x_k \neq x_{k-1}$ . Hence  $s_{\lceil k/2 \rceil}^T y_{\lceil k/2 \rceil} \geq \tau \mu_k^\delta \|x_k - x_{k-1}\|^2 > 0$ , where the second inequality is a consequence of  $\tau, \mu_k > 0$ . Thus, the curvature condition holds. Next, we show that (20) holds for  $k$ . It is well known that using the Sherman–Morrison–Woodbury formula,  $B_k$  is equal to  $B_{k,m}$  given by

(36)

$$B_{k,j} = B_{k,j-1} - \frac{B_{k,j-1} s_i s_i^T B_{k,j-1}}{s_i^T B_{k,j-1} s_i} + \frac{y_i y_i^T}{y_i^T s_i}, \quad i := \lceil k/2 \rceil - (m-j), \quad 1 \leq j \leq m,$$

where  $s_i$  and  $y_i$  are defined by (16) and  $B_{k,0} = \frac{y_{\lceil k/2 \rceil}^T y_{\lceil k/2 \rceil}}{s_{\lceil k/2 \rceil}^T y_{\lceil k/2 \rceil}} \mathbf{I}$ . Note that with  $j$  varying from 1 to  $m$ , the index  $i$  takes values in  $\{\lceil k/2 \rceil - m + 1, \lceil k/2 \rceil - m + 2, \dots, \lceil k/2 \rceil\}$ . First, we show that for any  $i$  in this range,

$$(37) \quad \tau \mu_k^\delta \leq \frac{\|y_i\|^2}{y_i^T s_i} \leq L + \tau \mu_k^\delta,$$

where  $L$  is the Lipschitzian parameter of the gradient mapping  $\nabla F$  given by Assumption 6(b). Let us define the function  $h(x) \triangleq F(x, \xi_{i-1}) + \tau \frac{\mu_k^\delta}{2} \|x - x_0\|^2$  for fixed  $i$  and  $k$ . Note that this function is strongly convex and has a gradient mapping of the form  $\nabla F + \tau \mu_k^\delta (\mathbf{I} - x_0)$  that is Lipschitz with parameter  $L + \tau \mu_k^\delta$ . For a convex function  $h$  with Lipschitz gradient with parameter  $L + \tau \mu_k^\delta$ , the following inequality, referred to as the cocoercivity property, holds for any  $x_1, x_2 \in \mathbb{R}^n$  (see [24, Lemma 2, p. 24]):

$$\|\nabla h(x_2) - \nabla h(x_1)\|^2 \leq (L + \tau \mu_k^\delta) (x_2 - x_1)^T (\nabla h(x_2) - \nabla h(x_1)).$$

Substituting for  $x_2$  by  $x_i$ ,  $x_1$  by  $x_{i-1}$ , and recalling (16), the preceding inequality yields

$$(38) \quad \|y_i\|^2 \leq (L + \tau \mu_k^\delta) s_i^T y_i.$$

Note that function  $h$  is strongly convex with parameter  $\tau \mu_k^\delta$ . Applying the Cauchy–Schwarz inequality, we can write

$$\frac{\|y_i\|^2}{s_i^T y_i} \geq \frac{\|y_i\|^2}{\|s_i\| \|y_i\|} = \frac{\|y_i\|}{\|s_i\|} \geq \frac{\|y_i\| \|s_i\|}{\|s_i\|^2} \geq \frac{y_i^T s_i}{\|s_i\|^2} \geq \tau \mu_k^\delta.$$

---

<sup>1</sup>If  $\nabla F(x_k, \xi_k) + \mu_k(x_k - x_0) = 0$ , then we can draw a new sample of  $\xi_k$  to satisfy the relation.

Combining this relation with (38), we obtain (37). Next, we show that the maximum eigenvalue of  $B_k$  is bounded. Let  $\text{Trace}(\cdot)$  denote the trace of a matrix. Taking trace from both sides of (36) and summing up over index  $j$ , we obtain for  $i := \lceil k/2 \rceil - (m-j)$ ,

$$\begin{aligned}
\text{Trace}(B_{k,m}) &= \text{Trace}(B_{k,0}) - \sum_{j=1}^m \text{Trace}\left(\frac{B_{k,j-1}s_i s_i^T B_{k,j-1}}{s_i^T B_{k,j-1} s_i}\right) + \sum_{j=1}^m \text{Trace}\left(\frac{y_i y_i^T}{y_i^T s_i}\right) \\
&= \text{Trace}\left(\frac{\|y_{\lceil k/2 \rceil}\|^2}{s_{\lceil k/2 \rceil}^T y_{\lceil k/2 \rceil}} \mathbf{I}\right) - \sum_{j=1}^m \frac{\|B_{k,j-1}s_i\|^2}{s_i^T B_{k,j-1} s_i} + \sum_{j=1}^m \frac{\|y_i\|^2}{y_i^T s_i} \\
(39) \quad &\leq n \frac{\|y_{\lceil k/2 \rceil}\|^2}{s_{\lceil k/2 \rceil}^T y_{\lceil k/2 \rceil}} + \sum_{j=1}^m (L + \tau \mu_k^\delta) \leq (m+n)(L + \tau \mu_k^\delta),
\end{aligned}$$

where the third relation is obtained by positive definiteness of  $B_k$  (this can be seen by induction on  $j$ , and using (36) and  $B_{k,0} \succ 0$ ). Since  $B_k = B_{k,m}$ , the maximum eigenvalue of the matrix  $B_k$  is bounded by  $(m+n)(L + \tau \mu_k^\delta)$ . As a result,

$$(40) \quad \lambda_{k,\min} \geq \frac{1}{(m+n)(L + \tau \mu_k^\delta)}.$$

In the next part of the proof, we establish the bound for  $\lambda_{k,\max}$ . The following relation can be shown (e.g., see [20, Lemma 3])

$$\det(B_{k,m}) = \det(B_{k,0}) \prod_{j=1}^m \frac{s_i^T y_i}{s_i^T B_{k,j-1} s_i} \quad \text{for } i := \lceil k/2 \rceil - (m-j).$$

Multiplying and dividing by  $s_i^T s_i$ , using the strong convexity of the function  $h$ , and invoking (37) and the result of (39), we obtain

$$\begin{aligned}
\det(B_k) &= \det\left(\frac{y_{\lceil k/2 \rceil}^T y_{\lceil k/2 \rceil}}{s_{\lceil k/2 \rceil}^T y_{\lceil k/2 \rceil}} \mathbf{I}\right) \prod_{j=1}^m \left(\frac{s_i^T y_i}{s_i^T s_i}\right) \left(\frac{s_i^T s_i}{s_i^T B_{k,j-1} s_i}\right) \\
&\geq \left(\frac{y_{\lceil k/2 \rceil}^T y_{\lceil k/2 \rceil}}{s_{\lceil k/2 \rceil}^T y_{\lceil k/2 \rceil}}\right)^n \prod_{j=1}^m \tau \mu_k^\delta \left(\frac{s_i^T s_i}{s_i^T B_{k,j-1} s_i}\right) \\
(41) \quad &\geq (\tau \mu_k^\delta)^{(n+m)} \prod_{j=1}^m \frac{1}{(m+n)(L + \tau \mu_k^\delta)} = \frac{(\tau \mu_k^\delta)^{(n+m)}}{(m+n)^m (L + \tau \mu_k^\delta)^m}.
\end{aligned}$$

Let  $\alpha_{k,1} \leq \alpha_{k,2} \leq \dots \leq \alpha_{k,n}$  be the eigenvalues of  $B_k$  sorted nondecreasingly. Note that since  $B_k \succ 0$ , all the eigenvalues are positive. Taking (39) and (41) into account, and employing Lemma 6, we obtain

$$\alpha_{1,k} \geq \frac{(n-1)! (\tau \mu_k^\delta)^{(n+m)}}{(m+n)^{n+m-1} (L + \tau \mu_k^\delta)^{n+m-1}}.$$

This relation and that  $\alpha_{k,1} = \lambda_{k,\max}^{-1}$  imply that

$$(42) \quad \lambda_{k,\max} \leq \frac{(m+n)^{n+m-1} (L + \tau \mu_k^\delta)^{n+m-1}}{(n-1)! (\tau \mu_k^\delta)^{(n+m)}}.$$

Therefore, from (40) and (42) and that  $\mu_k$  is nonincreasing, we conclude that (20) holds for  $k$  as well. Next, we show  $H_k y_{\lceil k/2 \rceil} = s_{\lceil k/2 \rceil}$ . From (36), for  $j = m$  we obtain

$$B_{k,m} = B_{k,m-1} - \frac{B_{k,m-1} s_{\lceil k/2 \rceil} s_{\lceil k/2 \rceil}^T B_{k,m-1}}{s_{\lceil k/2 \rceil}^T B_{k,m-1} s_{\lceil k/2 \rceil}} + \frac{y_{\lceil k/2 \rceil} y_{\lceil k/2 \rceil}^T}{y_{\lceil k/2 \rceil}^T s_{\lceil k/2 \rceil}},$$

where we used  $i = \lceil k/2 \rceil - (m - m) = \lceil k/2 \rceil$ . Multiplying both sides of the preceding equation by  $s_{\lceil k/2 \rceil}$ , and using  $B_k = B_{k,m}$ , we have  $B_k s_k = B_{k,m-1} s_{\lceil k/2 \rceil} - B_{k,m-1} s_{\lceil k/2 \rceil} + y_{\lceil k/2 \rceil} = y_{\lceil k/2 \rceil}$ . Multiplying both sides of the preceding relation by  $H_k$  and invoking  $H_k = B_k^{-1}$ , we conclude that  $H_k y_{\lceil k/2 \rceil} = s_{\lceil k/2 \rceil}$ . Therefore, we showed that the statements of (a), (b), and (c) hold for an odd  $k$ , assuming that they hold for any odd  $t < k$ . In a similar fashion to this analysis, it can be seen that the statements hold for  $t = 2m - 1$ . Thus, by induction, we conclude that the statements hold for any odd  $k \geq 2m - 1$ . To complete the proof, it is enough to show that (20) holds for any even  $k \geq 2m$ . Let  $t = k - 1$ . Since  $t$  is odd, relation (20) holds. Writing (20) for  $k - 1$ , and taking into account that  $H_k = H_{k-1}$ , and  $\mu_k < \mu_{k-1}$ , we can conclude that (20) holds for any even  $k \geq 2m - 1$  and this completes the proof.  $\square$

### 7.3. Proof of Lemma 8.

*Proof.* In the following, we show that the presented class of sequences satisfies each of the conditions listed in Assumption 4. Throughout, we let  $\alpha$  denote  $-(m+n)\delta$ .

- (a) Replacing the sequences by their given rules, we obtain

$$\begin{aligned} \gamma_k \mu_k^{2\alpha-1} &= \frac{\gamma_0}{(2^b \mu_0)^{1-2\alpha}} (k+1)^{-a} (k+\kappa)^{(1-2\alpha)b} \\ &\leq \frac{\gamma_0}{(2^b \mu_0)^{1-2\alpha}} (k+1)^{-a+(1-2\alpha)b}. \end{aligned}$$

From the assumption that  $\frac{a}{b} > 1 + 2\delta(m+n)$ , we obtain  $-a + (1 - 2\alpha)b < 0$ . Thus, the preceding term goes to zero verifying Assumption 4(a).

- (b) Let  $k$  be an even number. Thus,  $\kappa = 2$ . From (21) we have  $\mu_k = \mu_{k+1} = \frac{\mu_0 2^b}{(k+2)^b}$ . Now, let  $k$  be an odd number. Again, according to (21) we can write

$$\mu_{k+1} = \frac{\mu_0 2^b}{((k+1)+2)^b} < \frac{\mu_0 2^b}{(k+1)^b} = \frac{\mu_0 2^b}{(k+\kappa)^b} = \mu_k.$$

Therefore,  $\mu_k$  given by (21) satisfies (15). Also, from (21) we have  $\mu_k \rightarrow 0$ . Thus, Assumption 4(b) holds.

- (c) The given rules (21) imply that  $\gamma_k$  and  $\mu_k$  are both nonincreasing sequences. Therefore, we have  $\gamma_k \mu_k \leq \gamma_0 \mu_0$  for any  $k \geq 0$ . So, to show that Assumption 4(c) holds, it is enough to show that  $\lambda_{\min} \gamma_0 \mu_0 \leq 1$ , where  $\lambda_{\min}$  is given by (19). Since we assumed that  $\gamma_0 \mu_0 \leq L(m+n)$  for any  $\delta \in (0, 1]$ , we have  $\gamma_0 \mu_0 \leq (m+n)(L+\mu_0^\delta)$ , implying that  $\lambda_{\min} \gamma_0 \mu_0 \leq 1$  and that Assumption 4(c) holds.
- (d) From (21), we can write

$$\sum_{k=0}^{\infty} \gamma_k \mu_k = \gamma_0 \mu_0 2^b \sum_{k=0}^{\infty} (k+1)^{-a} (k+\kappa)^{-b} \geq \gamma_0 \mu_0 2^b \sum_{k=0}^{\infty} (k+2)^{-(a+b)} = \infty,$$

where the last relation is due to  $a+b \leq 1$ . Therefore, Assumption 4(d) holds.

(e) Using (21), it follows

$$\sum_{k=0}^{\infty} \gamma_k \mu_k^2 = \gamma_0 \mu_0^2 4^b \sum_{k=0}^{\infty} (k+1)^{-a} (k+\kappa)^{-2b} \leq \gamma_0 \mu_0^2 4^b \sum_{k=0}^{\infty} (k+1)^{-(a+2b)} < \infty,$$

where the last inequality is due to  $a+2b > 1$ . Therefore, Assumption 4(e) holds.

(f) From (21), we have

$$\sum_{k=0}^{\infty} \gamma_k^2 \mu_k^{2\alpha} \leq \gamma_0^2 (\mu_0 2^b)^{2\alpha} \left( \sum_{k=0}^1 \frac{(k+\kappa)^{-2\alpha b}}{(k+1)^{2a}} + \sum_{k=2}^{\infty} \frac{(2k)^{-2\alpha b}}{k^{2a}} \right) < \infty,$$

where in the first inequality, we use  $\alpha < 0$  and in the last inequality, we note that  $a+\alpha b = a-\delta(m+n)b > 0.5$ . Therefore, Assumption 4(f) is verified.  $\square$

#### 7.4. Proof of Lemma 9.

*Proof.* Throughout, we let  $\alpha$  denote  $-\delta(m+n)$ . Assumptions 5(a), (b), (c) and (15) have been already shown in parts (a), (b), (c) of the proof of Lemma 8.

(d) It suffices to show there exists  $K_0$  such that for any  $k \geq K_0$  and  $0 < \beta < 1$ ,

$$(43) \quad \frac{\gamma_{k-1}}{\gamma_k} \frac{\mu_k^{1-2\alpha}}{\mu_{k-1}^{1-2\alpha}} - 1 \leq \beta \lambda_{\min} \gamma_k \mu_k.$$

From (21) and the definition of  $\alpha$ , we obtain

$$\frac{\gamma_{k-1}}{\gamma_k} \frac{\mu_k^{1-2\alpha}}{\mu_{k-1}^{1-2\alpha}} - 1 \leq \frac{\gamma_{k-1}}{\gamma_k} - 1 = \left(1 + \frac{1}{k}\right)^a - 1 = 1 + \frac{a}{k} + o\left(\frac{1}{k}\right) - 1 = \mathcal{O}\left(\frac{1}{k}\right),$$

where the first inequality is implied due to  $\{\mu_k\}$  being nonincreasing, and in the second equation, we used the Taylor's expansion of  $\left(1 + \frac{1}{k}\right)^a$ . Therefore, since the right-hand side of (43) is of the order  $\frac{1}{k^{a+b}}$  and that  $a+b < 1$ , the preceding inequality shows that such  $K_0$  exists for which Assumption 5(d) holds for all  $0 < \beta < 1$ .

(e) From (21), we have

$$\begin{aligned} \frac{\mu_k^{2-2\alpha}}{\gamma_k} &= \gamma_0^{-1} (\mu_0 2^b)^{2-2\alpha} (k+\kappa)^{-b(2-2\alpha)} (k+1)^a \leq \frac{\gamma_0^{-1} (\mu_0 2^b)^{2-2\alpha}}{(k+1)^{-a+(2-2\alpha)b}} \\ &\leq \gamma_0^{-1} (\mu_0 2^b)^{2-2\alpha} = \rho, \end{aligned}$$

where the first inequality is due to  $\alpha < 0$ , and the second inequality follows by the assumption  $a \leq 2b(1+\delta(m+n))$ . Therefore, Assumption 5(e) is satisfied.  $\square$
